## PHYSICIAN DOES NOT BELIEVE IN ANTITOXIN—PATIENT DIES

That rare species of the "genus homo," the physician who does not believe in antitoxin is not yet extinct, is indicated in a report on a death from diphtheria received recently by the Division of Communicable Diseases. The patient, a girl of seven, was visited by the physician in question apparently on the second day of the disease. The physician stated that the child died of post-diphtheritic cardiac involvement, over a month later. No antitoxin was given, as he does not believe in it. According to the medical

directory published by the American Medical Association, this man graduated from the New York Homeopathic Medical College and Flower Hospital in 1907. As homeopathic medical colleges now teach the value of antitoxin in diphtheria, it is difficult to understand his failure to keep abreast of the times in such matters of life and death, especially when we consider that he received his medical diploma in comparatively recent years.

## PHYSICIANS OF UTICA ORGANIZE NEW SOCIETY

The physicians of the city of Utica announce the formation of the Utica Academy of Medicine, founded for the sole purpose of the advancement

of medical science. This organization has no connection with any hospital staff, nor does it propose to supplement any other existing organization.

# NEWS NOTES

## MEDICAL SURVEY NUMBER 11—MEDICINE IN ROCKLAND AND ORANGE COUNTIES, NEW YORK

**EDITOR'S NOTE** The information on which this Survey is based was supplied by Dr Ralph O Clock, President of the Medical Society of the County of Rockland, by Dr J D Mars, President, and Dr H J Shelley, Secretary, of the Medical Society of the County of Orange, and by Dr Frank W Laidlaw, District State Health Officer

### ROCKLAND COUNTY

Rockland County is located on the west side of the Hudson River, next to New Jersey. It has an area of 183 square miles, and a population of 45,548, according to the Federal census of 1920. A large proportion of the people are commuters from New York, and are grouped in four principal centers of population, each of which is served by a line of railroad. The station in the county nearest New York City is 24 miles distant, and the farthest is 35 miles. Travel is easy between the various sections of the county. While conditions in the county are rural, yet the influence of New York City is felt in medicine as well as in living conditions.

**Physicians**—The number of physicians practising in Rockland County is 52, grouped in 15 centers, according to the directory of the Medical Society of the State of New York. This gives one physician to every 865 of population. But since several New York City physicians are registered in their summer homes in the county, there is one physician to about every 1,100 people.

The Medical Society of the County of Rockland has 40 members, or 77 per cent of the physicians listed in the directory. The percentage would be practically 100 if only those in active practice were counted and summer residents from New York City were not listed.

The Medical Society holds five meetings annually, and the average attendance is over 75 per cent of the membership. Rockland County probably excels all others of New York State in the proportion of its physicians who are members, and in the proportion of members who attend the meetings. The utmost good feeling prevails among the physicians, and the standards of the practice of medicine are high.

The programs of the meetings are always practical. One meeting is held in Letchworth Village, and cases of mental defects are usually presented. Endocrine Disturbances was the subject of a recent meeting, and illustrative cases

were presented by Dr Walter Timme of New York. The programs have consisted of teaching clinics whenever possible.

A social supper is often served at the close of the meeting, and the annual meeting consists almost wholly of a dinner.

The dues in the County Medical Society were formerly two dollars, and were not sufficient to carry on the varied activities of the Society. At the last meeting they were raised to five dollars by the enthusiastic vote of the Society. One speaker said to the President, "We don't care how high the dues are, so long as you keep on giving us our money's worth."

There is a group medical society, called the Ramapo Clinical Club, which is composed of about fifteen physicians practising in Suffern and vicinity. It meets monthly in the evening at the homes of its members, and has a scientific program and a social supper.

The public health work of Rockland County is in charge of nine health officers who serve districts composed of ten villages and five towns. Each health officer serves an average population of 5,000 persons. Nearly all of the health officers have made a special preparation for their work by taking a health officers' course conducted by the State Department of Health.

A special feature of the public health work of Rockland County is the high standard of its milk inspection in Nyack and some other municipalities in which bacterial counts are made regularly and the results published.

**Hospitals**—Rockland County has two general hospitals. The Nyack Hospital is rated with a capacity of 26 beds, but it is usually overcrowded. The funds have been provided which will triple its capacity. The hospital has an excellent laboratory, and its staff does first-class surgical and medical work.

The Good Samaritan Hospital in Suffern has 30 beds.

The County supports a Tuberculosis Hospital of fifty beds.

The number of hospital beds available in Rockland County is about 22 in every 1,000 of population, but the number will be nearly doubled when the present building plan is completed.

There are seven public health nurses in Rockland County. Nyack has a nurse supported by the Board of Health of the village. The County has a tuberculosis nurse, a paper mill in Pierman has an industrial nurse, and there are school

nurses in Spring Valley, Hillburn, Suffern and West Nyack

The after-care of poliomyelitis and other orthopedic work among crippled children is supervised by a nurse who also works in the neighboring counties of Orange, Sullivan, Ulster and Greene

The tuberculosis work of Rockland County is very well done. It is centered in the Sanatorium, and is headed by Dr. W. J. Ryan, Superintendent of the Sanatorium, who conducts diagnostic clinics. The field nurse has listed seven cases for each annual death.

There is a county tuberculosis committee which derives its funds from the sale of Christmas Seals. It employed an executive secretary for six months last year to do educational and nutritional work.

The physicians of Rockland County have the advantage of a small area, with easy automobile communication, and easy access to the metropolitan center. They are of a high class, and the efficiency of the Medical Society reflects the favorable conditions under which the physicians live and work.

#### ORANGE COUNTY

While Orange County adjoins Rockland, the two counties are medically distinct owing to the peculiarities of transportation. The principal commuting railroad lines end in Rockland County, and the Ramapo and Bear Mountains shut off easy automobile traffic between the two counties, except to the northwest, where the main state road extends to Middletown, Port Jervis, and the center of the State.

Orange County has an area of 834 square miles and a population of 119,844, according to the 1920 Federal Census. It had only a small increase in population during the decade from 1910 to 1920, and the increase was confined to its three cities, while the rural sections and most of the villages decreased in value. Yet the people of Orange County are prosperous, and the industries of farming, dairying and horsebreeding are still actively carried on.

Orange County has three cities, as follows:

Newburgh	Population, 30,000
Middletown	Population, 18,000
Port Jervis	Population, 10,000
	<hr/> 58,000

These cities are the medical centers for the surrounding territory.

Orange County has 163 physicians grouped in 25 centers according to the Directory of the Medical Society of the State of New York. This gives one physician to every 670 population. But if the nine physicians on the Staff of the State Hospital and the physicians who are only summer residents are deducted, there would

be left about 145 physicians who are in actual practice, or one to every 900 of population.

There is a larger proportion of physicians in the cities than in the rest of the County, owing to the location of the specialists in the cities. The distribution of the physicians is shown in the following table:

Locality	Number of Doctors	Population	Ratio to Population
Newburgh	38	30,000	1 to 800
Middletown	34	18,000	1 to 530
Port Jervis	17	11,000	1 to 600
Total Cities	89	58,000	1 to 650
Rest of County	56	61,000	1 to 1,100

Orange County has an active County Medical Society with a membership of 106, or 73 per cent of the active practitioners of the County. The Society holds four meetings annually, and its programs are purely scientific. The leaders are planning to enlarge the activities of the Society and to institute a series of teaching clinics.

There is a local medical society, the Newburgh Bay Medical Society, which has 75 members drawn from Newburgh and the surrounding counties of Ulster and Dutchess. It holds six meetings annually. The program of each consists of a social supper followed by a scientific discussion.

Middletown has a Physicians' Club which is a factor in unifying the local profession.

The hospitals of Orange County are as follows:

Name	Location	Number of Beds
Thrall	Middletown	40
Middletown Sanatorium	Middletown	40
Warwick	Warwick	20
St. Luke's	Newburgh	100
Tuxedo	Tuxedo	25
Deerpport Sanatorium	Port Jervis	30
St. Francis	Port Jervis	55
Goshen	Goshen	25
Odell Memorial	Newburgh	48
		<hr/> 383

The total number of hospital beds available in Orange County is 383, or 3.2 beds in every 1,000 of population.

The larger hospitals are well managed and conform to the standards of the American College of Surgeons.

The three physicians who organized the Warwick Hospital made an earnest attempt to develop group medicine, but the experiment was abandoned owing to the difficulty of securing a sufficient number of specialty cases in a village of 2,500 people.

The official public health work of Orange County is done by a health officer in each city and by a health officer in each of the 12 villages and 20 towns, but there are only 21 health officers, for some serve more than one unit. Each

health officer outside the cities serves an average of 3,000 population

A special feature of the public health work is the extent to which toxin-antitoxin has been given to school children for protection against diphtheria. This procedure has been extensively followed in Newburgh, Middletown, Port Jervis, Goshen, Chester, Florida, and Otisville, and has been done at the spontaneous request of the local school authorities, backed by the local health officers and physicians.

Orange County has 13 public health nurses, as follows

County T B nurse	1
Newburgh	4
Port Jervis	2

Middletown	2
Chester	1
Goshen	1
Monroe	1
Walden	1

Of these, four are school nurses and four are under the Board of Health.

Tuberculosis work is well done in Orange County. The Odell Memorial Hospital in Newburgh is the County Tuberculosis Hospital, and the County maintains a field nurse. Diagnostic Clinics are held in various parts of the County under the auspices of the State Department of Health, assisted by local health officers and physicians. F O

### BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society, held at Hollywood Gardens, 896 Prospect avenue, on April 15, 1925, was called to order at 9 p m, the First Vice-President, Dr Edward R. Cuniffe, in the Chair.

Drs Isidore Berger, Moses Lewis Furman, William H. Godsick, Isaac Goldstein, S. Carlyle Trattler, were elected to membership.

Reports of committees being called for, Dr Lukin reported for the Committee on Medical Economics. At the conclusion of the reading of the report, Dr Lukin moved that the secretary be instructed to write Dr S. S. Goldwater a letter of commendation, and expressing the hearty support of our Society with regard to his paper on "The Extension of Hospital Privileges to All Practitioners of Medicine," published in the March 28th issue of the Journal of the American Medical Association. This motion was carried.

Dr Friedman, for the Committee on Public Health, reported on the subject of periodic health examinations, and announced that the next meeting of the Society will be in the form of a mass meeting, at which this subject will be fully discussed.

Under New Business, Dr Gitlow moved that the Comitia Minora's recommendation be concurred in, that there be an annual assessment of one dollar per member for the purpose of defraying the expenses for literature, etc., in connection with the committee's work on behalf of periodic health examinations.

Dr Magid, on behalf of several members of the Society, proposed several amendments to the By-Laws.

It was ordered that the proposed amendments be printed in the next issue of The Bulletin.

Dr Rostenberg moved that a letter be sent to Dr Alexander Goldman, expressing the sympathy of the Society on the death of his son. This motion was carried.

Dr Keller appealed to the members on behalf of The Bulletin, with particular reference to the necessity of securing advertisements.

The scientific program, arranged by The Bronx Pediatric Society, then proceeded as follows:

Pathogenesis of Tuberculosis in Childhood (with lantern slide demonstration)

Prof. Bela Schick

Discussion by Drs Fisher, J. B. Cohen and Lukin. The discussion was closed by Dr Schick.

Dr Rost moved that the Society extend a vote of gratitude and thanks to Dr Schick. This motion was carried, and Dr Cuniffe expressed the thanks of the Society to Dr Schick.

The Chairman, Dr Cuniffe, announced that at the next meeting the question of periodic health examinations will be considered and urged the members to be present.

The meeting adjourned at 11 p m.

Respectfully submitted,

I. J. LANDSMAN, M.D.,  
Secretary

nurses in Spring Valley, Hillburn, Suffern and West Nyack

The after-care of poliomyelitis and other orthopedic work among crippled children is supervised by a nurse who also works in the neighboring counties of Orange, Sullivan, Ulster and Greene

### REUNION AND DINNER OF THE MEDICAL OFFICERS OF THE WORLD WAR

An attractive feature of the Annual Meeting of the American Medical Association at Atlantic City will be the reunion of the medical men who served their country in the Army and Navy during the World War, to renew the memories, friendships and associations of those eventful days The Chief Surgeon of the A E F will be there, and the President of the Association of Military Surgeons, Surgeon General Hugh E Cumming, and other officers of the Association under whose auspices the meeting will be held An effort will be made to group together those

who served in the same organizations and so it is requested that reservations be made as early as possible, and that comrades state in writing for them the base hospital or other medical unit to which they belonged Write for tickets to Colonel Burt R Shurly, Med-Res, U S A, 62 West Adams Avenue, Detroit, Mich

Time and Place May 27th at 7 P M at the Ritz-Carlton Hotel, Atlantic City

Members of the Association of Military Surgeons are requested to wear the badge of the Association

## ROCKLAND COUNTY MEDICAL SOCIETY

The first stated meeting of the year of the Medical Society of the County of Rockland was held on the afternoon of Thursday, April 23rd, in the new Recreation Room of the County Tuberculosis Sanatorium, Summit Park. Twenty-one members and six guests were present.

Dr R O Clock, the President of the Society, announced the death of Dr W F Kaufmann of Haverstraw, from erysipelas following a mastoid operation. Resolutions of appreciation were passed by the Society.

The subject of the meeting was Tuberculosis. Rockland County has always done its anti-tuberculosis work well. The County Medical Society has promoted the construction and maintenance of the Sanatorium, and a physician, Dr George A Leitner, of Piermont, is President of its Board of Managers. Clinics are held regularly, and field work is done by a nurse employed by the County. There are seven cases listed and visited for every annual death. With such a record as this, the physicians were prepared to take a deep interest in a program devoted to Tuberculosis.

The principal speaker was Dr James Alexander Miller, Director of the Tuberculosis Department of Bellevue Hospital. His subject was "The Early Diagnosis and Sanatorium Care of Tuberculosis," and was both informative and inspirational—an ideal combination for an address before a meeting of physicians.

Dr Miller appealed to the physicians to keep tuberculosis in mind always in dealing with patients who show only mild symptoms of chronic fatigue and indigestion. He described a typical routine of events in which these patients have recurrent attacks of a mild disorder, such as indigestion. A doctor gives them some medicine, and they are "cured" for a time, and then the symptoms return because they are due to the toxemia of a mild tuberculosis. These cases usually get well permanently when they are treated for tuberculosis, but many develop advanced tuberculosis because tuberculosis is often the last instead of the first thing that doctors think about when they examine the cases.

Dr Miller urged the doctors to use the Sanatorium for the treatment of cases in the earliest possible stage. He closed his lecture with an interesting series of lantern slides showing the value of X-ray photographs in the diagnosis of mild pulmonary tuberculosis which gives few or no physical signs.

The very great value of Dr Miller's address was the simplicity of his language and the clearness of his thought. A physician listening to him feels that tuberculosis cases are no rare mysterious conditions that rich organizations like to monopolize, but that his own intimate patients have the disease, and that it is his duty to recognize and treat it.

The substance of Dr Miller's address was printed on page 188 of the February 6th, 1925, issue of this Journal as a part of the symposium on Periodic Health Examinations conducted by the Medical Society of the County of New York.

Dr Robert L Plunkett, Director of the Division of Tuberculosis of the State Department of Health, described the diagnostic clinics of the State Department of Health, and emphasized the fact that they were held in co-operation with the local physicians.

Dr Orrin S Wightman, Associate Editor of THE NEW YORK STATE JOURNAL OF MEDICINE, spoke on the doctor's responsibility to take a deep interest in tuberculosis and other chronic conditions, and not to permit lay organizations to usurp the field which physicians can control far better than anyone else.

Dr W J Ryan, Superintendent of the Sanatorium, described the newer phases of the work in the institution.

At the close of the meeting a supper was served which enabled the physicians to get together and discuss their personal problems. The President took the opportunity to urge the physicians to show their good fellowship by attending a dinner on May 7th, to be given to Dr W R Sitler of Suffern, on the fiftieth anniversary of his graduation in medicine.

F O

## WOMEN'S MEDICAL SOCIETY OF NEW YORK STATE

The One Hundred and Nineteenth Annual Medical Meeting has so many attractive and interesting events that we can assure our Syracuse friends of one of the largest conventions the State Medical Society has ever had.

Besides the splendid program provided by the State Medical Society and the attractive entertainment for the wives and friends of the physicians, the Women's Medical Society of New

York State, Nineteenth Annual Meeting is to be held in the Hotel Syracuse, Monday, May the Eleventh.

Invocation—Eliza M Mosher, M D

Address of Welcome—Elizabeth L Shrumpton, M D, Chairman, Committee of Arrangements

Greeting—Owen E Jones, M D, President, Medical Society of the State of New York

Response President's Address—Julia Kimball  
Qua, M D

"Alkaline Reserve and Acidosis"—Isabel M  
Meader, M D, Watertown

# THE DAILY PRESS

Our pile of daily press clippings this week is larger than ever, but they are exceedingly commonplace, both in content and in form. They are statistical rather than informative, and many bear all the earmarks of having been dragged by eager reporters from unwilling doctors and boards of health. The week seems to have been an off one for news of a medical nature, or of a kind that bears even remotely on medicine.

The clipping readers seem to have standards of their own. Senator Copeland was a former health officer, and so everything he says relates to health, according to the clipping bureau readers.

May Day as Child Health Day comes in for whole columns of clippings, every one of which emphasizes the fact that Herbert Hoover is the President of the National Child Health Association. The May Day articles have a great sameness and bear all the marks of having been written in one office and syndicated throughout the land.

We wonder why the local health officials don't write up Child Health Day from a local point of view, and give it a personal appeal to the people of their community. We recall that our old school reading book had a picture of an eager mother throwing her happy baby into the Ganges River where a blinking crocodile waited expectantly for his meal, but that did not inspire us with any desire for baby saving—it all seemed so commonplace and far-away as a dull movie. What is needed in medical publicity is an appeal which reaches each particular community.

The lay organizations promoting Child Welfare, anti-tuberculosis work, and other health measures are not spending 10 per cent of their energies in reaching physicians. If they would devote 90 per cent of their energies and funds to influencing physicians, and would endow medical organizations so that physicians could do effective preventive work, would not the use of preventive medicine make a tremendous advance? We know of county medical societies which are already undertaking advanced public health work, but lack the funds to carry it on effectively. It would seem that an endowment of these societies by a lay organization would produce far better results than attempts to establish an organization that is independent of the practicing physicians of a community.

So far as publicity goes, we seldom see a clipping stating that a county medical society is leading in public health work, and yet we know that

several are doing so—as for example the Jefferson County Society whose activities we have frequently recorded. What physicians do is all in their commonplace daily work, and they do not publish the details of their civic practice of medicine any more than they do their private practice.

The practice of civic medicine necessarily requires publicity, for it is largely done by organized medical societies, and publicity is necessary to carry the news to the great mass of members of the society, and to hold their interest so that they will pay their dues to support the work. Publicity is also necessary in order to get the people to vote money for public health, to build hospitals, to finance health departments, and to support other measures which constitute the practice of civic medicine.

We have made a rather extensive acquaintance among reporters, and have found them anxious to give reasons and explanations of health matters which they report. They wish to make every news item so interesting that people will talk about it, and ask for more news on the subject. Doctors will always find reporters receptive to explanations which they give. If doctors would comment on the medical news of the day, the health items in the daily papers would be far more interesting than we have found them to be during the last week or two.

The Mineola Times, April 3rd, contains two items of health news which have a great local appeal. One is an account of a meeting of the Parent Teachers' Association of the Village in which particular items of advice were given, such, for example, as the following:

"Mrs. Beatty spoke on the dangers lurking in the use of a common drinking cup and cautioned the children against swimming in Simonson's Pond west of Marcellus Road as the water is polluted by drainage from the village streets."

The meeting also took a definite stand in regard to serving milk in the school.

"The question was brought up of the advisability of serving milk to the younger children during school hours. Records of other schools in Nassau County indicate it has been beneficial. A motion was passed to bring this matter before the school board for their approval. Young children grow restive and inattentive during the morning hours and other schools have found a glass of milk refreshes and fortifies the children. This is no reflection on home care and feeding,

but is a condition of childhood when a little nourishment given often is better than large meals at longer intervals"

We commend the newspaper because reporting definite items of health advice which are given in civic medicine are like a personal prescription given to a patient in private practice

---

The second item in the Mineola paper is a column and a half article on the proposed Preventorium for Tuberculous Children to be added to the County Sanatorium. Dr A J Davis, Superintendent of the institution, gave an interview in which he described the need of preventive work among children. The interview closes

"Much if not all tuberculosis begins in childhood. We do not at present know whether the adolescent disease is a lighting up of an old process or a new super-imposed infection. But in either case, childhood is the most important period in the history of the disease, because it is the true incipient stage—the very beginning of nearly all tuberculosis

"It is very important to recognize and to watch children who are infected, for if we are to stamp out the disease we must attack it here—in its real, incipient stage. Such children do very well under watchful care, but without it, they may do very badly. If we accept the common view that a positive tuberculin reaction means nothing except in infancy, we lose our greatest opportunity in combating the disease in its inmost stronghold—when we have our best chance of wiping it out"

---

How many cases does it take to make an epidemic? The death of a four-year-old child from rabies in New Rochelle has led the health authorities of the adjoining city of Mount Vernon to require that the preventive inoculations against rabies shall be given to all dogs in the city. There seems to be a disposition of the health authorities and the newspapers to minimize the existence of rabies in New Rochelle, although the same papers say the disease is prevalent in other parts of Westchester County, in Rockland County, and in Connecticut. They admit it is all around the city, but the *New Rochelle Star*, April 16th, says

"A local quarantine would not be effective. In his opinion the community would benefit from a quarantine only if dogs were ordered muzzled throughout Westchester and Rockland counties, in both of which there has been an unusual number of cases this spring. If such a move is contemplated, it is entirely up to the state department. The state authorities receive immediate reports of all cases and are in a position to

handle the situation. If they order a quarantine, all dogs not muzzled will be corralled and shot by state health officers. In this city the rabies has not reached epidemic proportions by any means, with only one case reported"

One human case of rabies in a city and many known cases of rabies in dogs in the surrounding territory! What more is necessary to constitute an epidemic of rabies?

The Mount Vernon *Argus*, April 23, says

"All dogs in Mount Vernon must be immunized to prevent rabies or else they will be shot. Dr William H Purdy, health commissioner, arrived at this decision today after discussing the question of a quarantine with Dr William S Corlis, veterinary surgeon and inspector of the local health department

"The process of immunization, as explained by Dr Corlis, is the injection of a vaccine into the dogs to prevent them from contracting the disease. Each dog must be vaccinated by a representative of the health department and a tag showing that the animal has been so treated will then be attached to the regular license. No date for such an order becoming effective has been fixed"

The city authorities of Mount Vernon are to be highly commended for their active efforts to control rabies

---

Cases of poisoning by cream puffs continue to appear frequently in the metropolitan papers. We do not know whether the cases are actually developing often, or the reporters have got it into their heads that every obscure gastro-intestinal outbreak is caused by cream puffs. It is strange that cream puffs are always the guilty food. However, the following report from the *New York Mirror*, March 24th, has all the appearance of reliability

"Simultaneous with the removal of four more persons to the Reception Hospital yesterday suffering from food poisoning. Health Commissioner Monaghan announced that the source of the food had been located. A total of 12 persons have been stricken within the last few days. Seven are in the hospital

"It was found by Health Department authorities that all those suffering from the poisoning had purchased cream puffs from a bakery in East 96th Street. They believe that the poisoning was due to bacteria as the shop was reported to be unsanitary

"Samples of the pastry and the ingredients used were taken for chemical and microscopic analysis

"The cream puffs were eaten at a party"

# BOOK REVIEWS

**HOW IS YOUR HEART?** Intimate Talks on the Prevention of Heart Disease and on the Care of an Already Damaged Heart By S CALVIN SMITH, M.S., M.D. 12mo of 208 pages New York, Boni and Liveright, 1924 Cloth, \$1.75

This is a small book written with the object of educating the layman as to the causes, prevention and general management of heart disease. The author's style of writing is entertaining and lucid with a dash of humor. Unlike some books of its general type, it is not a bore for the physician to read this one, indeed he may do so with profit, as the views expressed are those held in the best repute today.

The influence of faulty habits in causing heart disease is discussed, especially the one of overeating. This is well explained, also the influence of lack of exercise, harmful habits of thought and previous illnesses. A chapter is devoted to the influence of infected teeth and another one to the tonsils.

The author's views regarding tobacco and alcohol are sane and conservative. He believes that the former in moderation does not make a good heart bad but may make a bad heart worse. His paragraphs on "defending the companion of our solitary hours" are satisfactory and have the ring of truth.

The book is free from fads, dietary and other, and may be safely recommended to the intelligent layman. The perusal of books of this type should cut down the number of believers in foolish cults.

W E McCOLLOM

**THE HAPPY BABY** Editorial Advisor, Dr L. EMMETT HOLT Contributors Dr L Emmett Holt, Dr Harvey J Burkhart, Dr Ralph Lobenstine, Dr Henry L K. Shaw 12mo of 120 pages New York, Dodd Mead and Company, 1924 Cloth, \$1.00

The articles composing this book were published in one of the lay magazines for women, "The Delineator," and are by different authors, namely Dr Holt, Dr Harvey J Burkhart, Dr Ralph Lobenstine and Dr Henry L K Shaw.

Dr Holt has written chapters on "General Care of the Baby," "Maternal Nursing," "Artificial Feeding," and "Diet Problems of Childhood." Dr Shaw contributes a chapter on "Early Childhood" while Dr Lobenstine takes up "The Care of the Expectant Mother and the New Baby," and Dr Burkhart writes on "The Child's Teeth."

The lay press has done a great deal to spread the gospel of health and nutrition especially with regard to children, its publications reach a vastly greater percentage of the people of any country than any medical or scientific writings. Furthermore the real hope of overcoming malnutrition and dental cares and other results of improper hygiene and feeding lies in educating the mother of young children. For many reasons, then, such articles as the ones here considered must be productive of an enormous amount of good.

WM HENRY DONNELLY

**PRACTICE OF PEDIATRICS** By CHARLES GILMORE KERLEY M.D., and GAYLORD WILLIS GRAVES, M.D. Third Edition, revised and reset Octavo of 922 pages with 150 illustrations Philadelphia and London, W B Saunders Company, 1924 Cloth, \$9.00

This new edition of this well known work has been brought up-to-date in most subjects and contains many valuable hints on treatment. The book is well printed in large enough type so as to make easy reading, on good paper and is well bound. It can be highly recommended as a standard text book on this subject. P L P

**MODERN ASPECTS OF SYPHILIS** By M J HORGAN, B.A., M.B., B.Ch., B.A.O., NUI 12mo of 136 pages. London, Henry Frowde and Hodder & Stoughton, 1923 Cloth, \$1.75 (Oxford Medical Publications.)

This book of 136 pages is engagingly written in a brisk style, and considering its size is surprisingly full of valuable information. It is a successful "effort to reproduce the standpoints of the Vienna School." There is an adequate index and reference list. Compared to the standard practice of American authorities the doses of arsenicals advised are small and the duration of treatment, particularly in early cases, too short. Bismuth and tryparsamide are not mentioned. Despite these reservations the work will repay the time of the reader.

GRAY PHILLIPS.

**FUNDAMENTAL PRINCIPLES IN TREATMENT** By HARRY CAMPBELL, M.D., B.S., F.R.C.P., Lond., Senior Physician West End Hospital for Nervous Diseases Wilham Wood & Co, New York, 1924 Price, \$4.00

The writer has given us a scholarly treatise upon the many factors which enter into the care of patients. He considers not only the sick individual, but his surroundings and social condition. The physician himself comes in for an amount of instruction concerning himself and his manner of treating individuals. This carefully prepared book would benefit anyone who studies it, as the fundamental principles of treatment are frequently omitted or slighted in the medicinal treatment of patients.

H. M. M

**THE EFFECTS OF INANITION AND MALNUTRITION UPON GROWTH AND STRUCTURE.** By C M Jackson, M.S., M.D., LL.D., Professor and Director of the Department of Anatomy, University of Minnesota. 117 Illustrations P Blakiston's Son & Co, Philadelphia, 1925 Price, \$8.00

Human famine has become so frequent of occurrence since the beginning of the World War that a study of the effects of inanition and malnutrition is a matter of great practical importance. This volume may be taken as an authoritative monograph on this subject. It offers a comprehensive consideration of the results of malnutrition. The bibliography is extensive and the completeness with which the current literature has been covered is commendable.

HENRY M FEINBLATT

**MANUAL FOR DIABETICS** By GLADYS L. BOYD, M.D., and MARION D STALSMITH Introduction by F G BANTING, M.D., 12 mo Cloth, 101 pages Price, \$1.50 net. Funk & Wagnalls Company, Publishers 1924

This is a useful small book to place in the hands of the patient to relieve the physician of some of the burden of instruction. The chapters of which there are eight, deal with insulin, food in diabetes, weights and measures, complications of diabetes, examination of the urine, tables of food values, diabetic recipes and menu planning.

The book is very well arranged and compares favorably with the others of its type. It may well be recommended to diabetic patients.

# NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

Vol. 25, No. 17

NEW YORK, N. Y.

JUNE, 1925

## PRESIDENT'S ADDRESS \*

By OWEN E. JONES, M.D.,

ROCHESTER, N. Y.

SOMETIME in the world's early history, where man, clothed with intelligence, became afflicted with some of the ills to which he became heir, art, if not the science, of medicine soon found a field for its activities, as history records that about 4500 years B. C., in the ancient city of Memphis one Imhotep, who was the physician to the King, became widely known for his skill, and people came from afar to obtain his counsel and care, his influence moulded the medical teaching and practice of that time, thus with the advance of time at various periods in the world's history there stood out to illuminate the path of medical practice and teaching such men as Aesculapius, Galen, Herodotus and Hippocrates, whose teachings and practices became the standard of medical ethics which today largely govern our relationship between the physician and patient.

And thus down through the various epochs of time the physician has played his part in the world's history by ever devoting his time and energies in caring for the ills of mankind, thoughtful ever of the best interest of those whom he served.

Owing, however, to the brilliant mind of Hippocrates, medicine early became a science of its own among the Greeks, and for centuries Greeks exercised almost a monopoly on medical knowledge throughout the civilized world. The Greek physicians were honored as among the most highly educated people of their times and our knowledge of early medicine is almost entirely due to their observations and writings. Prior to the time of Celsus, who lived about the time of Christ, the practice of medicine among the Romans was considered the least desirable of all professions. The employment of a physician was postponed when possible and only resorted to, if at all in the last extremity. The Roman had great faith, however, in the power of

his gods, of which he had a great selection. For every common disease there was a god or tetish. Celsus was not a physician, but one of the most learned men of his time and wrote extensively on many subjects of learning. His writings on medicine, fortunately for us, were not lost through the middle ages and were among the first medical works to be printed after the invention of printing.

Without undue strain upon our imagination it is not difficult for us to group the people about us into two classes representing to the physician and his profession the attitudes of the ancient Greeks and Romans. There are those who, like the Greeks, consider the practice of medicine a science and an art and avail themselves of its advantages, while the other group, like the ancient Romans, take great pride in their physical fitness and boast that they are immune from disease and when stricken rely upon their constitution to overcome their affliction, calling a physician only when death stares them in the face. Except during the lethargy of the middle ages, the physicians have ever striven to increase the group of those who would scientifically care for their bodies, but with indifferent results. Today, owing to our general advance in education, the average individual has an infinitely greater knowledge of his own body and its function and is less inclined to be impressed by superstition and fetish than he was at any time in the past. Also many powerful influences are stimulating the prevention of disease and the preservation of health by scientific measures.

The physicians, through their medical organizations, have an unequaled opportunity now of freeing the practice of medicine from its medieval shackles and advancing it to the position in society where the physician will rightly receive recognition as the representative of the most important of all professions. There are a number of ways in which this Society can aid its members in realizing their ideal—the practice of preven-

\* Delivered at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 14, 1925.

tive medicine The first step which has received considerable attention in a number of groups including several County Societies, is that of developing among the laity the practice of having physical examinations made upon themselves at regular periods A committee should be appointed to study the methods employed and the results obtained by those in this Society and in other organizations who have endeavored to develop the practice of periodic examination The Society should develop facilities for aiding the physician in equipping himself for intelligently making and recording such examination This is such a new feature in medicine that no effort has been made by medical schools to teach the subject as such and hence the concept of the work is exceedingly vague in the minds of most physicians and even considerable variance will be found among those who have clear ideas as to what the term embraces

During the past year we have endeavored to bring the importance of this subject to the physicians throughout the State We have referred to it invariably on our visits to County Societies and have been pleased to observe the eagerness with which the physicians have taken up this subject

There are a number of encouraging signs that we have noted in the Society during the past year, to which we desire to call your attention There is an abundance of evidence of an increase of interest among the physicians in their County Societies This is an exceedingly healthful condition and we have done what we could to encourage it Several Societies have notified us of resolutions passed to increase the number of meetings held annually Several have undertaken through their committees on public health and public education, the publication in local papers of articles of medical interest for the instruction of the people At least half a dozen counties have adopted a scheme or have appointed committees who are preparing a method for the periodic physical examination of apparently well people

The Committee on Legislation during this year advanced markedly its consolidation of the County Societies in an effort to secure favorable legislation and prevent the passage of bills inimical to the practice of medicine The legislature itself by its action upon bills introduced, reflected a recognition of this unity in the medical profession

The Scientific Committee has undertaken an innovation in its program for the annual meeting by the development of a clinic and demonstration on a particular subject for the third day of the meeting

The special Committee on Post-Graduate Medical Instruction has made a thorough study of

schemes and methods employed in other states for the extension of medical education from the hospitals and medical schools to the practicing physician This report should not only be accepted and recorded, but should form the basis of some definite activity during the next year There was never such a demand from the physicians actively engaged in the practice of medicine for the establishment of facilities that will keep them in touch with centers of learning and with large hospitals and laboratories, as there is today

The special Committee on Nursing has also made a very careful study of a subject that demands immediate attention from this Society The problem of providing adequately trained nurses for all of the positions which they are called upon to fill today, is an important one and attempts at its solution have been undertaken by a number of different groups, but should not be solved without the co-operation of the physicians, because fundamentally, nurses have been trained to be assistants to the physicians and whether eventually they are employed as bedside nurses or public health nurses, as general nurses or specialized nurses, they, nevertheless, must take direction from the physician and, therefore, the Society should use its influence to have the report of this special committee developed

In the past the chairmen of our standing committees have found it exceedingly difficult to accomplish the programs they laid out This is largely due to two factors, first, that the members of the committees are always practicing physicians who have little time that they can actually spare for the work, and, second, that the tenure of office of the members of the committee is entirely too short to accomplish marked constructive work, but now that we have employed an executive officer, one of whose functions it will be to serve *ex-officio* on such committees and to continue from one year to another the execution of programs outlined, we can expect greater results of our standing committees whose programs have called for co-operation with the County Societies

The Committee on Legislation, with its three years of experience, has conclusively proven the advisability of having a standing committee ally itself intimately with a similar committee in each of the County Societies, and I would recommend that this plan be considered by the standing committees of Public Health and Medical Economics

Our County Society must be its own judge as to its membership and the qualifications of those admitted to membership but I would urge that more attention be given to the keeping up and increasing membership There are practicing within this State 16,000 physicians, only 10,500 of whom are members

of County Societies. Among these 5,500 non-members there must be many men who would be valuable additions to their respective County Society. The problems of the County Society are receiving considerable attention in medical circles today. In my opinion the secret of success for any County Society lies in the interest which the members take in its functions. A Society should not limit itself and its interest to its meetings, but should take an active interest in all activities within its jurisdiction that have relation to the practice of medicine and health education. Physicians receive a license from the State to practice and this license, it seems to me, not only confers the privilege of practicing his profession, but also a duty to assist the State with his knowledge in its protection of its citizens.

The State Society can and should aid the County Societies in developing the social and civic side of their program as keenly as it does their scientific program.

In addition to increasing their membership the County Societies should be stimulated to increase the number of their meetings. Thirty per cent have but two meetings a year and another 40 per cent do not meet more than four times a year, thus fewer than 30 per cent of the Societies meet six times a year or oftener. One Society has monthly meetings, four others have ten meetings annually. I realize that in many instances, where the County Society has so few meetings, it is largely due to the fact that the physicians are members of other medical organizations which meet more frequently. A scheme should be devised, however, by which the County Society as such would meet more frequently. It could be done by holding its meeting in conjunction with some of the other groups, allowing the other group the privilege of presenting the scientific program, and the County Society take some time for the transaction of its business.

Just as the County Society should familiarize itself with and function at least in an advisory capacity on all medical activities undertaken within its County, so the State Society should manifest an interest and assert its prerogative in consulting with all lay organizations, whether voluntary or governmental, whenever they engage in State-wide activities which relate to the practice of medicine or the

conservation of public health. Our absence from such conferences in the past has been noted, and we have been charged with indifference or even unwillingness to cooperate with those endeavoring to promote public health measures. There may be a question in the minds of some as to the advisability of our Society thus taking an active interest in things other than the immediate practice of medicine, but the right of the individual to protect himself against disease cannot be denied him and who is better qualified to advise with him in the measures he may wish to take than the practicing physician, and to whose interest will such measures react more directly than to the physician's?

Is it not as unfair to expect any group of citizens, no matter how highly educated or what regard they may have for the physicians and their profession, to be able to act wisely on questions requiring medical decision as it would be to expect physicians to give legal decisions? Our unwillingness to express ourselves clearly and forcibly where the practice of medicine is involved, has led to much confusion among the laity.

It is also quite reasonable to expect that the human being who now realizes the necessity of calling a physician when he feels his end approaching, will eventually, under the present scheme of education, be equally eager to call a physician when the earliest symptoms of disease or sickness appear, or even seek his advice and care in preventing sickness, a condition which we are hopeful will result from our present activity in stimulating periodic examinations.

In all of our activities it is well for us to bear in mind that we compose the largest Medical Society in the world, and that also within our State are located 688 hospitals, 11 medical schools and 2 post graduate schools, the world's largest research institute and more than 100 diagnostic laboratories, the most advanced State Department of Health and the largest number of most highly endowed philanthropic organizations. With these facilities for advancement we should constitute the most effective medical unit the world has ever known. I think we realize our position and believe that we have started a program which will give our Society a unique place in future medical progress.

## THE DOCTOR OF THE FUTURE \*

By GEORGE E VINCENT, Ph D,

President Rockefeller Foundation

LET me at the outset disavow any idea of forecasting definitely or dogmatically the future of the medical profession. One can hope only to enumerate conditions and tendencies of the present and to raise rather than to settle questions as to the probable effects of these things in the coming years.

The outlook, of course, varies with different countries. Racial, economic, social and political conditions affect medical service in a variety of ways. There can be no uniformity of development. Kinds of doctors and services appropriate to widely diversified environments will appear in different parts of the world. This address will deal with the outlook for such countries as the United States and Canada.

The rapid increase of scientific medical knowledge, experience, and technical resources is causing obvious changes. Medical education costs a great deal more in time and money. The modern doctor is dependent as never before on laboratory, hospital, and complicated and costly means of diagnosis and treatment. The specialist has become a necessity. No one person can control the whole range of knowledge and technique.

The present situation with regard to American population groups and the kinds of medical service they are receiving may be roughly described as follows. The mass of the population (perhaps 75 to 80 per cent) are treated by general practitioners who have limited technical appliances, little or no specialization of skill, and slight relation to medical services organized in hospitals, dispensaries, and clinics. The rich and well-to-do (perhaps 5 per cent) receive attention from specialists who depend primarily upon their own individual equipment, who have little connection with institutional medicine, but provide a high degree of specialized skill. The poor (perhaps 15 to 20 per cent) are under the charge of organized practice, that is, doctors who have access to institutional equipment, offer a high degree of specialization, and are fairly well connected with hospital, dispensary, and health center services.

There are forces at work which will gradually modify this state of things. Thus, preventive medicine in reducing the amount of sickness is limiting curative practice, in many areas typhoid fever, which used to be prevalent, is rare, malaria is yielding to comprehensive measures of control, and other communicable diseases which used to afford a good deal of practice are being steadily reduced in amount.

Again, the high cost of sickness is causing changes. There is a growing demand that this cost be distributed over large population groups.

The principle of insurance against sickness is being applied in different ways. In some countries the state system of compulsory insurance has been adopted. Elsewhere, hospital associations and sick benefit societies are, for a small weekly or monthly fee, guaranteeing free care in case of illness. Industrial groups are providing medical hospital care in return for small sums deducted from the wages of employees and supplemented by contributions from the companies. Such developments, which are multiplying rapidly, have a bearing upon the future of the medical profession.

Changed conditions affect the geographical distribution of physicians. The unwillingness of doctors to settle in the country and a tendency towards concentration in the towns and cities is unmistakable. The countryside is, on the whole, failing to replace the pioneer practitioners of an earlier generation. The truth is that men with modern training are not attracted to rural practice. They are not satisfied with the income. They want hospital connections, professional comradeship and, for their families, the opportunities of education, society, and recreation which towns and cities afford. There is no reason to suppose that a cheaper, more "practical" kind of medical education would turn out doctors who would be willing to go to the country.

There is another factor which must be reckoned with. A credulous public opinion permits the spread of cults, quackeries, and fanaticisms which increase the difficulties of well-trained and conscientious physicians. Modern medicine depends for its success upon a public that understands and appreciates. It must be admitted that the medical profession is not wholly blameless for the gullible state of the public mind. Neglect of the psychic side of medicine, failure to help educate individuals and public, narrowly conceived professional policies, shortcomings in the knowledge, skill or integrity of some doctors have had their part in producing the present situation. The chief responsibility, however, rests with the whole educational and social system. It is reflected not only in the popular attitude towards medicine, but in that towards science generally and in all forms of thinking and feeling.

Out of conditions such as those that have been enumerated no one type of doctor will, of course, emerge in the future. There are now pretty clearly recognized kinds of physicians. They fall into four groups: (1) the professorial doctor, who teaches and investigates, (2) the specialist, (3) the socialized or full-time salaried doctor, and (4) the individual, independent general practitioner.

The teachers and investigators will always form an element relatively small in numbers, but of

\* Abstract of an address delivered at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 13 1925

vital importance. They will give more and more time to research and instruction. While a few will give all their time to such duties, the larger number will continue private consultations which will have a bearing on their teaching and investigative work.

The specialist is an inevitable outcome of the growth in knowledge, experience and technique. In all probability there will be a steady increase in the numbers and in the prestige of doctors of this kind. They are likely to be better organized and to have private clinics and hospitals, although for the time being the tendency towards group practice seems to have received a check. Standards of specialized efficiency are likely to be formulated and increasingly enforced. Voluntary professional associations will do something. University degrees will do more. State requirements may ultimately prescribe standards when these have been worked out by the profession and by university medical schools. There may be delay, but the time will surely come when only tully qualified and certified surgeons, for example, will be legally permitted to perform major operations.

The institutional salaried doctor has come to stay. Army, Navy, hospitals, dispensaries, asylums, industries, school systems, insurance companies are multiplying the demand for men and women who will devote themselves exclusively to social service on a salaried basis. Already a considerable percentage of the medical profession sustain a whole or a part-time relation to institutions.

In spite of the growth of the other types, the individual general practitioners constitute by far the largest group of doctors, perhaps 75 per cent of all. Except in emergencies the great mass of the population look to the general practitioner. When the word doctor is mentioned, it is he who comes to the mind of the average citizen.

The well-trained, properly equipped, experienced general practitioner of ability, character, personality, is a fundamentally valuable person. He is a good diagnostician. He sees his patient as a whole. He knows his peculiarities and circumstances. He can decide when to refer him to a specialist and when to protect him against the very real danger which is threatened by a narrowly specialistic point of view. He cheers and encourages, or warns and commands. He is not only a physician, but a friend and counsellor. He is a good citizen and an asset to the community. Too much cannot be said in praise of the individual general practitioner of the best type.

The problem of the American doctor in the future largely resolves itself into this: can the general practitioner be reproduced on a high level of efficiency, and can he survive under the conditions which he is likely to face in the future? These questions involve at once medical education and the organization of medical service.

There is widespread dissatisfaction with the medical curriculum. Critics say that it is too crowded, too theoretical, that the student is "spoon fed," given too little opportunity to think for himself and to develop initiative. There is too much tendency to have in mind the training of medical scientists and specialists rather than of the general practitioner. Reformers are insisting upon a thorough-going revision, upon a reduction in kinds and amount of instruction, upon a clear differentiation between undergraduate training which should aim at turning out the general practitioner and graduate training which should be reserved for the medical scientist and the specialist.

The general practitioner will survive only on the terms upon which any social functionary holds his own. He must gain social esteem or prestige, and be able to make a living. Many assert that the general practitioner is doomed to disappear, that his opportunities are being constantly restricted so that in the future he will be unable to win confidence and a livelihood.

It may be admitted that the general practitioner as now equipped and related to the profession faces serious and probably increasingly difficult handicaps. He is over-shadowed by the prestige of the specialist. He cannot as an individual afford the cost of modern equipment and technical resources. In the case of perhaps half of the general practitioners there is no genuine hospital connection which affords opportunity for continued education and professional stimulus. The growth of institutional and of preventive medicine is constantly encroaching upon the ordinary fields of curative medicine.

The disappearance of the general practitioner would be a serious loss. Such an outcome is not to be contemplated without deep concern. The underlying American philosophy of individualism with its insistence upon independence, initiative, ambition, seems to be embodied in the general practitioner. Are there ways in which he may readjust himself to the new and changing social situation?

The general practitioner may hope to survive if he will submit to a measure of organization and team-play in the co-operative use of laboratories and other resources, in meeting the demand for spreading costs of sickness over large groups through readjusted forms of compensation, and especially if he will become a practitioner of preventive medicine.

The doctor may make a place for himself as a counsellor of health. Personal hygiene will always remain the largest part of a public health program. After the environment has been sanitized and communicable diseases subjected to the maximum control, there will remain the vast field of personal health for which no organized public functionaries can assume responsibility. If the

general practitioner will recognize this opportunity, if medical schools will prepare him for the service, if the community will recognize his value in this new relationship, an inspiring career of opportunity and usefulness will open up before him. This will mean, however, a gradual change of attitude, an increasing interest in the normal, a study of the effects upon health of diet, exercise, mental attitudes, recreation, family and social life. All the finest qualities which have made the general practitioner successful in the past may be trained to even greater account in the future.

In view of all these contingencies, a confident prediction would be hazardous. The public demand for efficient service, for special skill, for reduced costs, is likely to increase. Gradually—very gradually—public intelligence and discrimination may improve. It is to be hoped that in time people will give more than lip service to the ideal of prevention. The day may come when men will treat their bodies almost as wisely as they do their motor cars.

In such circumstances a better and more economical organization of medical service will be inevitable. No thoughtful person can welcome the extension of state medicine beyond the legitimate and necessary field of public health activity. But, if private initiative and voluntary co-operation fail, it may be impossible to resist the demand for governmental intervention. This has happened in Germany and England, in backward

colonial possessions, and even in new European states. A persistent social need will demand satisfaction, if not in one way, then in another.

The medical profession, then, has a heavy responsibility and an inspiring opportunity. Will it recognize the tendencies of today and the demands of tomorrow? Will it take the long view, the socially conscious attitude? Will it see that the best service must be made available to the great masses of the people on terms that they can afford to meet, that no medical mechanism can efficiently replace skilful and sympathetic human care and guidance, that prevention of disease must be more and more a dominant motive, that the general practitioner, if he is to survive, must be readjusted to new times, trained, esteemed and rewarded as a vital factor in the medicine of the future?

You will rightly reply that the responsibility rests only in part on the medical profession. You will properly ask: "Will family life, schools, colleges, universities, the press, the platform, social standards, public opinion, offer an environment in which well-trained, wisely organized, and high-minded doctors can do their work honestly and efficiently, protected against ignorance, prejudice, and fanaticism?" Yes, it is a social problem which involves our whole civilization. To analyze it is not to solve it. We can only hope that clearer vision may kindle imagination and strengthen resolution.

---

## THE ANNUAL MEETING

The One Hundred and Nineteenth Annual Meeting of the Medical Society of the State of New York was held in Syracuse for four days, beginning on Monday, May 11, 1925. This meeting was one of the best that was ever held. We are tempted to say that it was the very best, but in the progress that has been made in every branch of medicine, it would be expected that the standards of the meetings of the State Medical Society should be progressively higher and higher.

The total registration was 1,229, which is an extremely high figure.

The headquarters of the Society were in the Hotel Syracuse, and the entire tenth floor was given over to the Society. Nearly all the meetings were held on that floor, and the management was excellent. The principal mistakes were those of judging the size of the audiences of the sections, and in assigning a proper room to each. However, the errors were excusable, for the attendance in most sections was larger than previous experience had suggested.

All the commercial exhibits were in the corridors of the tenth floor, and were readily accessi-

ble to the doctors. They seemed to be well patronized by the visiting physicians.

The opening session was that of the House of Delegates, which met on Monday afternoon and evening and Tuesday morning. The legislative machinery functioned perfectly with Dr. E. Eliot Harris as the fatherly genius who kept all parts in motion without friction. The House of Delegates in his hands was like an orchestra under an expert leader. There was no doubt who was doing the leading, or that perfect harmony was produced to the great satisfaction and enjoyment of the players.

An unusually wide range of topics was discussed, and practically all the recommendations of the officers and committees were adopted. Graduate Education seemed to be the big new feature which is being promoted by the State Medical Society, and, after all, the education of physicians to practice modern aspects of medicine is the principal object of the State Society.

Harmony and good feeling prevailed throughout the deliberations of the House of Delegates. When a discussion of the annual registration of

physicians took place on Monday evening, and it seemed to indicate that the physicians were divided over a minor point which concerned themselves alone, the speaker wisely excluded everybody except the accredited delegates, and the discussion ended amicably without even smoke being produced

The principal business of the House of Delegates consisted in receiving the reports of the officers, referring them to reference committees for consideration, and acting on their recommendations. The final actions of the House of Delegates fixed the policies of the Medical Society of the State of New York for the coming year. The policies adopted were all in the line of progress, and will be found set forth in the minutes which are printed in this issue, page 802.

The annual dinner was held on Tuesday evening, and was notable for its large attendance, its sociability, and its excellent speeches. (See report on page 762.)

The formal Annual Meeting took place on Wednesday evening. Some may wonder why that evening's ceremonies were called the Annual Meeting. The Charter of the Medical Society of the State of New York requires that an annual meeting shall be held, but it does not say what kind of a meeting it shall be. The custom has been to make the formal annual meeting a popular one to which the public is invited. The principal features of this year's meeting were a practical address by the President, Dr. Owen E. Jones, on "The State of the Society," and an address by Dr. George E. Vincent, on "The Doctor of the Future." These addresses are printed on pages 755 and 758 of this JOURNAL.

The meetings of the several sections were unusually well attended, and the programs were carried out practically as they were announced in the JOURNAL of April 3rd. Nothing new of a spectacular nature was announced, but the speakers set forth the modern ideas of medical practice along their special lines.

The papers read before the several sections became the property of the Medical Society of the State of New York, and will be published in the JOURNAL during the coming year.

The new feature of devoting the last day of the meeting to the general consideration of one subject proved a great success. Tuberculosis was the topic chosen, and all phases of the disease and the methods of its control were shown practically as was announced in the April 17th issue of this JOURNAL. Specimens, both gross and microscopic, and X-ray photographs, were on exhibition, and methods of heliotherapy were illustrated by pictures and by happy children clad in breech cloths.

A special feature of the day was the exhibition of a moving picture film showing the development of the disease in the body, and the methods of detecting and combating it. This film was pre-

pared by Dr. L. Gregory Cole, of New York City, and required an hour to show. It is available for tuberculosis committees throughout the state, through the American Medical Films, Inc., 350 Madison Avenue, New York.

Another feature was a new invention called the multiple stethophone, by means of which a whole room full of students may listen to the sounds of the lungs and heart at the same time. It consists of an amplifier like that used in radio, and from it wires lead out to the audience, and each listener connects his stethoscope to a sounder like the ear-piece of a radio outfit. The room in which this device was shown was constantly crowded to its utmost capacity.

A scientific session relating to tuberculosis was held in a room which was packed while a big crowd waited outside. The attendance was unexpectedly large, and over 150 physicians registered for the day only.

The Committee, who successfully planned and conducted the demonstration, consisted of Dr. Edward R. Baldwin, Superintendent of Trudeau Sanatorium, Saranac, Dr. Harry A. Bray, Superintendent of the State Tuberculosis Hospital at Ray Brook, Dr. Harry J. Brayton, Superintendent of the Tuberculosis Sanatorium of Onondago County, Dr. William E. Lawson, Director of Tuberculosis Work of Albany County, and Dr. John J. Lloyd, Superintendent of the Monroe County Tuberculosis Sanatorium.

The success of the tuberculosis demonstration has led the Scientific Committee of the State Society to consider holding a similar demonstration on syphilis next year, and demonstrations on other diseases in the succeeding years.

The thanks of the Society are due to Dr. Frederick H. Flaherty and his associates on the Committee of Arrangements, for the perfection of the arrangements for the comfort and convenience of the visiting doctors and their wives. Everybody had a good time and will want to come to Syracuse again.

The peculiar function of the Executive Editor was to act as press agent to the reporters of the newspapers. The reporters of the four Syracuse dailies were extremely kind and considerate. We took them into our confidence, and they fully respected it, and we take this opportunity to extend the sincere thanks of the Medical Society of the State of New York to them and to the editors of the papers for their kindness and consideration.

We also thank the physicians who kindly gave their time in explaining medical movements to the reporters. We asked several prominent medical men to explain the doctors' point of view regarding nursing, mental clinics, and other popular movements in medicine, and we believe the kindness of both the interviewed and the interviewers resulted in a closer contact of the medical men with the newspapers and the public.

## MEETING OF THE SECRETARIES OF COUNTY MEDICAL SOCIETIES

A special feature of the meeting of the Medical Society of the State of New York was a dinner and conference of the secretaries of the county medical societies on Wednesday noon. A few of the secretaries had met at dinner during previous annual meetings of the State Society, and had maintained an organization, but nothing practical had come from it. Formal notices were sent out this year by Dr J S Lawrence, Executive Officer of the State Society, inviting all the secretaries to be present at this conference and dinner. Those who responded were

Dr John H Steward, Chenango County  
 Dr L A Schiff, Clinton County  
 Dr A. M. Loope, Cortland County  
 Dr William B Brooks, Herkimer County  
 Dr W S. Atkinson, Jefferson County  
 Dr A D Jaques, Nassau County  
 Dr D S Dougherty, New York County  
 Dr William Hall, Jr, Oneida County  
 Dr J S Thomas, Queens County  
 Dr B R Wakeman, Steuben County  
 Dr Frank Overton, Suffolk County  
 Dr W A Moulton, Tioga County  
 Dr Wilbur G Fish, Tompkins County  
 Dr F H Voss, Ulster County

Dr S J Banker, Washington County  
 Dr Harrison Betts, Westchester County  
 Dr F J Snell, Niagara County

Dr Van Etten, the newly elected President of the State Society, Dr Dougherty, the new Secretary, and Dr Harris, Speaker of the House of Delegates, spoke of the importance of the office of Secretary of every county medical society, and considered a meeting of the secretaries of great importance. A resolution was passed that the Council of the State Society be asked to authorize a formal meeting of all the secretaries some time next Fall.

A tentative organization of the secretaries was perfected with Dr Harrison Betts, President, and Dr J S Thomas, Vice-President.

The secretaries of county societies are the leaders who keep things moving in their organization. A good secretary is worth his weight in gold, and it is to the credit of many of the societies that they keep their secretaries in office year after year. Some have rounded out twenty-five years of service, and are still going strong. The proposed meeting of the secretaries of the county societies is an extremely good sign of progress in the affairs of the Medical Society of the State of New York. F O

---

## THE ANNUAL DINNER

An evening devoted to a formal dinner is one of the features of every annual meeting of the Medical Society of the State of New York. The dinner this year was held in the Grand Ball Room of the Hotel Syracuse, and was one of the most enjoyable and profitable that has ever been held. The room was filled to overflowing, and extra tables had to be provided. The service was excellent, and the hotel managers are to be congratulated on the pleasing manner in which they provided for an unexpectedly large gathering.

The program of the after-dinner speaking was as follows:

Toastmaster, Dr F H Flaherty, Syracuse, Chairman of the General Committee of Arrangements.

Address, Dr Owen E Jones, President of the Medical Society of the State of New York.

Greetings from Dr Nathan B Van Etten, newly elected President of the Medical Society of the State of New York.

Address, Chancellor Charles W Flint, of Syracuse University.

Address, Thurman ("Dusty") Miller, Editor of the *Daily News Journal*, Wilmington, Ohio.

Address, Hon James A Hamilton, Commissioner of Labor of the State of New York.

Dr Owen E Jones spoke of the increased interest shown by physicians generally in the county medical societies, and in the State Society, and called attention to the faithful work of the various officers and members of committees of the Medical Society of the State of New York.

The address of Dr Van Etten was, in fact, a brief inaugural statement—the only induction ceremony provided by the custom of the State Society. Dr Van Etten said that the new president always found the policies of the Society formulated and stabilized by the former president, and that he would be gratified if he could continue the lines of work that have already been happily outlined by his predecessor, Dr Jones. But new problems develop in the natural evolution of medicine, and the new president hoped to do more than ride the crest of the most advanced wave of new administrative measures, he wishes to swell the quiet tide of permanent progress.

Chancellor Flint, who was a former minister of the Gospel, compared the work of a pastor with that of a physician, and pointed out their similarity in seven respects.

1 Both originated in magic

2 Both have the motive that is stated by Dr Osler, in his history of medicine "Medicine arose out of the primal sympathy of man for man, to help those in sorrow and distress"

3 They have a common philosophy Both the priest and the physician come face to face with life and its varied relations When they see the body at its worst, and the soul beclouded by bodily imperfections, they either grow proud, materialistic, and cynical, or become humble co-workers with the Eternal in seeking to perfect the human race

4 Both have a sacrificial quality The martyrs to science are as holy as the martyrs to creed Physicians are always to be found who are willing to lay down their lives in order to show the way of life to others

5 Both share in an altruistic aim—not to be ministered unto, but to minister

6 Both have a moral régime, but the code of ethics of physicians is more highly developed than that of any other profession The splitting of fees, for example, is perfectly legal, but it is not at all ethical The Hippocratic Oath is a high obligation to service, and some of its phrases are of daily application, as, for example, this "With purity and holiness I will pass my life and practice my art" A physician who takes that oath seriously is close to the Kingdom of Heaven, but if he assumes it hypocritically, he is nearer the gates of Hell

7 Both professions seek to develop the spiritual side of man's nature Religious convictions, attitudes, and instincts have a direct effect on the mental and emotional status and indirectly on physical conditions No one can be a complete man unless he has a spiritual nature No one can delegate it to another, but each must

experience it himself The spiritual is significant to the physician because it sets free inhibitions, and broadens and prolongs life The perfection of the physical means the release of the soul that it may give real satisfaction Any one who would help mankind must have an awareness of the spiritual in order to render the best service

In closing, the Chancellor said "I salute you physicians as co-workers with the Eternal in perfecting the master-piece of the creation"

The burden of the speech of "Dusty" Miller (he said all millers were dusty) was strikingly like that of Chancellor Flint, but it was given in a diametrically opposite manner While the Chancellor's message was like a grand oratorio, that of Miller was like a simple Sunday School song Miller kept his audience in an uproar of laughter for half an hour while he talked on the theme "I do" at the rate of three hundred words a minute to the accompaniment of apt stories that flowed like a rippling brook He gave some extremely powerful doses in honeyed form, and the doctors cried for more.

"Dusty's" speech centered around three ms which he said might keep you out—indecision, indifference, and intolerance, and as he developed his sermonette, there were some physicians who were so unkind as to name others whom it hit He divided members of medical societies into the "Poor Me" group and the "I Do," and closed with the words of the wise men to Solomon's son, Rheoboam "If thou wilt be a servant to these people and serve them, then they will be thy servants"

Commissioner Hamilton described the work of the Labor Department in improving the living conditions of laborers, and said that eighty per cent of the work of the Department was medical

## ANNUAL REPORTS

### 1924

#### REPORT OF THE SPEAKER

##### *To the House of Delegates*

May I call the attention of the House of Delegates to the responsibility that devolves upon its members—less than two hundred in number—charged with the general management, superintendence, and control of the Society and its affairs and authorized to legislate in the interest of over ten thousand members of the Society throughout the State. As to the method of conducting this important business, the Speaker would be glad to receive constructive criticism from the members regarding the method of the work of the House of Delegates, in the hope that it may become more and more efficient in meeting the duties and obligations imposed by the Constitution and By-Laws.

The House of Delegates should emphasize as of first importance that the individual members of the medical profession of the State should be properly informed of the aims, purposes and accomplishments of the Society and the many advantages of membership therein, as the State Medical Society represents the strength of the organized profession.

It is the duty of the Councillors to visit the County Societies of their districts at least once a year, and I feel that the House of Delegates in the past has not given sufficient encouragement and support to the Councillors who are specially delegated to bring the message of organized medicine to the local societies of the State. Heretofore the reports of the Councillors have been referred to the reference committees without being read, and little attention has been given to the work of the District Branches and their Component County Societies by the House of Delegates. Let us study, aid and support the work of the Councillors and County Societies. We are fortunate in having a progressive and efficient executive officer in Dr. Joseph S. Lawrence, who has the ability and personality to splendidly cooperate with the Councillors and county societies in their work of bringing the message of organized medicine to the local physicians and public, with a result of adding desirable physicians to our membership and

weakening the public support of the cults, your consideration of the question would be timely.

The reports of the standing committees should receive careful attention by the members of the House of Delegates. The discussion of their reports and the final action thereon should reflect the deep interest and careful study of the work of our standing committees. I might cite in corroboration the work of the Committee on Legislation in bringing to the notice of the several counties of the State the importance of understanding and acting effectively on the many medical bills which come before the Legislature each year. The improvement exhibited in the mental grasp of the Legislative work by the county committees at their yearly meetings with the State Committee on Legislation is very evident to those who have watched the growth of the good work inaugurated by the chairman, Dr. James N. Vander Veer. The House of Delegates should request that other standing committees should also extend their work by cooperating with county societies of the state.

The sum of money derived from the increase of dues will give the council and the executive committee opportunity to extend the usefulness of the Society along lines voted by the House of Delegates. Although the House of Delegates does not appropriate any money the council is charged in Section 24 of the By-Laws with carrying out and giving full effect to any resolution or vote of the House of Delegates but such resolution or vote must not contain an appropriation of money. Within the past few years it has been found necessary to raise the dues of several of the State societies. For your information, I shall mention some of those which have come to my notice. In 1923 Oregon raised the dues from \$5 to \$20 a year. Wisconsin in 1923 raised annual dues from \$4 to \$9. Texas and Arizona each raised its dues to \$15 annually. The representatives of the states that have increased the annual dues agree that where the dues are trivial, the value of the State society to its members is correspondingly small, and that the improved quality of the service rendered

by the State Society justifies the increased dues to its membership. Some of the State Societies are considering the question of following the lead of the Texas State Association which has established a Board of Trustees for the purpose of studying and controlling the finances of the Association, such as investments, budget and all appropriation of money.

As the County Societies uphold the State Society, so should the latter support the American Medical Association by endeavoring to increase its fellowship in this State. I recommend that the President appoint a committee large enough to conveniently canvass the State in the interest of adding to the fellowship of the American Medical Association. At the last meeting of the House of Delegates the recommendation of the speaker authorizing the removal of the petty redundancies from the State law relating to the Medical Society of the State of New York was adopted. As a beginning Mr Whiteside prepared a bill which was presented to the Legislature repealing the clause which required the Society to elect annually the Censors of the Society—that bill passed both Houses and was signed by the Governor. I recommend the striking out, as not now being necessary, of the last sentence of Article SIX of the Constitution as follows: "The House of Delegates shall elect them annually," and Section 17 of the By-Laws "The Censors shall be nominated as provided in Article SIX of the Constitution and elected by a majority vote without ballot." The amendment cannot be considered this year, but is to be recorded as a proposed amendment to the Constitution and By-Laws to be acted on next year.

It is quite unnecessary to write a eulogy for the House of Delegates upon the work of Miss Lily D. Baldwin, who this year completes twenty-five years of giving her best self to the State Medical Society. If there be any member not acquainted with her work, he should visit the office of the State Society and see for himself the perfect organization that Miss Baldwin has at her command. There are complete files of letters written and received which are available at any mo-

ment, the Treasurer's department includes lists of all members who have paid as well as those who have not paid their dues, the Secretary's department shows classified records and general and special correspondence files, lists of physicians registered in the county clerk's office kept up to date, the data of each registered physician revised each year for the purposes of the Medical Directory, a list of the Fellows of the American Medical Association, not the least is the files of accumulated decisions on medical preparations offered for advertising. Miss Baldwin conducts a large amount of correspondence in answer to inquiries from officers, members of committees and secretaries of county societies. She has entire charge of the advertising in the Journal and Directory, she assists the editor in classifying papers, reading the proof, making up the Journal and mailing it to the members and she manages all the work connected with the publishing of the Medical Directory. She directs all business of the annual meetings of the Society and of the House of Delegates, in short, Miss Baldwin is the general manager and supervisor of all the business of the State Society, and she certainly knows the work. Miss Baldwin is always present and is most helpful at the meetings of the council and executive committee, and she prepares the budget for the executive committee and the council. For all this work she has no title, therefore I recommend that Miss Lily D. Baldwin be authorized to use the title of General Supervisor of the Medical Society of the State of New York as a reward for many years of good, faithful, obliging and efficient service to the Society.

The consideration and support the Speaker has received from the members of the House of Delegates is cordially acknowledged, and please be assured that they add to the pleasure of functioning as presiding officer.

Respectfully submitted,

E. ELIOT HARRIS,

*Speaker*

April 15, 1925

The Reference Committee approved all the recommendations of the Speaker, and in addition it recommended that an honorarium of five hundred dollars be given to Miss Baldwin for her faithful and efficient services (see page 804).

## REPORT OF THE PRESIDENT

### *To the House of Delegates*

In reviewing the activities of the Medical Society during the year which has just passed into history, we are gratified to note that there has been manifested a substantial and healthy growth in keeping with the Society's past traditions and highest ideals. While no particular activity was, perhaps, of sufficient importance to make it stand out above the rest, this is largely due to the fact that the general advancement has been so evident.

I am very happy to report that prompted not only by my own observations, but by comments of others, a very desirable spirit of harmony pervades the entire Society today. The efforts of the State Society in past years to bring about a clear understanding of the mutual relationship between the County Societies and the State Society, are developing in a very encouraging manner. This condition may be considered more remarkable, too, considering that it was feared by some that raising the dues of the State Society would tend to discourage membership in the County Societies. That this fear was unfounded is abundantly proven by the fact that the State Treasurer has received the dues of a larger number of members this year, to date, than he had received at the same date last year. The increased finances of the Society have enabled it to broaden its field of activities and the first step has been in the direction of cementing the relationship with the County Societies and encouraging the same among themselves.

### COUNTY SOCIETIES

There is a marked increase of interest manifested by the County Societies. During the year five different Societies have notified us of their intention to increase the number of meetings held annually. All of them have either considered a program or have adopted a scheme which they are now developing into a program for promoting physical examinations of the apparently well among their patients. Some have undertaken membership campaigns, an activity which should be urged upon every Society. There are in the State more than 16,000 physicians and only about two-thirds of these are members of the Society. While each County Society is the judge of its own membership and should be encouraged to maintain its standards, admitting to membership only those physicians who are adequately qualified, yet there must be among the 5,000 physicians in the State who are not members, many whose membership would be a credit to any Society. These should be sought out by the individual County Societies and their affiliation encouraged. One County reports 73

out of 75 physicians as members of the Society. Twenty others have at least 75 per cent of the physicians in their Counties enrolled in the Society.

More County Societies should be encouraged to increase the number of meetings held annually. Approximately 30 per cent of them have as few as two meetings a year, while another 40 per cent have four meetings a year, thus only 30 per cent hold bi-monthly meetings. It is conceivable that the interest of the Society may be increased by an increase in the number of meetings.

### COMMITTEES

The Committee on Legislation has continued its splendid work through another year. Its success in consolidating the interests of the County Societies through the conferences it has held with the chairmen of the Legislative Committees of the County Societies, was more marked this year than ever before and proves conclusively that similar activities undertaken by other committees are desirable.

Too much credit cannot be given to Dr. James Vander Veer for his loyalty and enthusiasm. He has cheerfully made an inestimable sacrifice in order that the Society's interests might be protected and advanced in the legislature. Realizing deeply the hardship that serving on this committee has meant to Dr. Vander Veer, I am, nevertheless, constrained to urge that he be persuaded to continue the chairmanship for another year.

The Committee on Scientific Work deserves commendation for its activity. It has by a great deal of effort prepared this year an unusually interesting and instructive program.

All of the special committees were unusually active and I want especially to call your attention to the reports of the special Committees on Medical Education and Nursing, and urge that steps be taken to realize the features they recommend.

### THE JOURNAL

The JOURNAL is steadily increasing in popularity and usefulness. It has increased its value to the physicians by its timely editorials and its special sections on legal medicine, public health and County Societies. Another section is to be added in the near future which will make the JOURNAL the equal of any of its contemporaries.

The medical surveys undertaken by the executive editor have been an exceedingly valuable feature and should be continued until the entire State is covered.

### LEGAL DEPARTMENT

We are greatly indebted to our counsel, Mr. George W. Whiteside, for services he has rendered during the past year. His remarkable success in our defense continues undiminished, but the demands upon him are growing so rapidly that they will soon outgrow his capacity. His services have not been limited to pleading our cases before the courts, but we are greatly indebted for his wise guidance and judgment both personally in our committee meetings and through his excellent articles in the columns of the JOURNAL.

I wish to take this occasion to urge that every member of the Society, if he has not already insured himself against loss from malpractice suits, do so at his earliest opportunity. Every member of our Society should possess such insurance for his own protection.

### EXECUTIVE OFFICER

During the year, Dr. Joseph Lawrence, who had been with the Department of Health, was appointed to the position of executive officer, provision for which had been made by your body at the last annual meeting. He began his duties the first of November. By the reports which reach me, I am convinced that we have done wisely in creating this position, and believe that it is one of the most important steps the Society has taken in recent years towards successfully amalgamating the County Societies and the State Society into the great Medical Society we should constitute. The work he has accomplished has justified the wisdom of those through whose efforts it became possible for the creation of this office.

There are certain recommendations I should like to offer.

My first recommendation is that the JOURNAL should be published semi-monthly throughout the year, providing sufficient funds are available, except during the session of the legislature, when its weekly publication, as was the custom in the past two years, should be resumed.

amount of work, both in detail and in the execution.

The second recommendation pertains to the manner of electing a president. It is a serious handicap for any man to assume the duties as president of this Society who has not had an opportunity of familiarizing himself with the great task of a broad general program, that the presidency in this Society entails.

To keep pace with our ever increasing duties and obligations to those whom we serve, it appears to me that this can better be done by making certain changes in the Constitution and By-Laws of our Society which will provide for the creation of the office of a President-elect.

My third recommendation is that the Society provide for itself a Board of Trustees, whose duties will be to study the needs and guide and control the expenditure of the Treasury's funds, the reasons for which must be apparent to all.

I therefore recommend that the President be empowered to appoint a committee, including our legal counsel, to take the necessary steps to so change our Constitution and By-Laws whereby this can be brought about.

In closing this, I wish to express to you my great appreciation for the high honor you have conferred upon me by electing me to the Presidency of the Society. The performance of the duties of this office have been made pleasant by the courteous and hearty support and cooperation received from all with whom I have been associated.

I shall always recall with much pleasure the cordiality extended to me by the County Societies and the District Branches which I have visited. My one regret is that time did not permit me to visit all of them.

I am moved by a deep feeling of gratitude for the assistance and aid given me by every officer of this Society and the loyal support I have received in the discharge of my duties.

OWEN E. JONES,  
*President*

April 15, 1925

The Reference Committee approved the suggestion that the JOURNAL be published semi-monthly, and that steps be taken to establish the office of President-elect and to create a Board of Trustees for the Society (see page 805).

## REPORT OF THE TREASURER

CHARLES GORDON HEYD, *Treasurer*, In Account with THE MEDICAL SOCIETY OF THE STATE OF

## REPORT OF THE SECRETARY

*To the House of Delegates*

In compliance with Section 37 of the By-Laws, the Secretary submits the following report for the year ending December 31st, 1924 —

Membership, Dec 31, 1924	9,567	
New Members, 1924	694	
Reinstated Members, 1924	332	10,593
		<hr/>
Deaths	134	
Resignations	40	
Expulsions	2	176
		<hr/>
		10,417
Dropped for non-payment of dues, Dec 31, 1924		385
		<hr/>
		10,032
Elected after Oct 1, 1924, and credited as of 1925		212
		<hr/>
Membership, Jan. 1, 1925		10,244

The membership on January 1, 1925, is the largest every attained, it shows an increase of 496 over the year previous. Of the members dropped during 1923 more than two-thirds have been reinstated. It is a pleasure to report that in spite of the increase in the State assessment, the dues received by the State Treasurer are in excess of those received at the same date last year.

The list of honor counties whose membership shows all dues paid for the year is as follows: Columbia, Essex, Franklin, Herkimer, Greene, Lewis, Montgomery, Oneida, Richmond, Schuyler, Steuben and Tioga.

One of the most important acts of the Society during the year, and one which promises much for the future has been the appointment of an Executive Officer. He has assisted the Chairman of the Committee on Legislation during the Legislative Session and has devoted the remainder of the year to visiting the county societies. He has assisted the officers in perfecting and carrying out plans for the betterment of the organization and he has stimulated the interest of the individual members. His appointment has been fully justified and his work has been valuable and important.

The Committee on Legislation deserves the highest praise, it has done most efficient work during the year and has kept the members of the Society thoroughly informed in regard to bills introduced in the Legislature.

I would like to call the attention of the House of Delegates to the condition of the Treasury.

Legislation enacted in the House of Delegates last year raised the dues. This resulted in doubling the income of the Society in the present calendar year. Such a sudden and large income always results disastrously. There are those members who opposed the increase in dues and who now feel that the receipts will so far exceed the

expenditures that a reduction in dues should be contemplated. There is another class of members who feel that a large surplus warrants greater and more radical expenditures. There is still another class of members, who, as a result of a doubled income, are prepared to vote increased salaries to many connected with the Society. These three classes who threaten the treasury have all formulated plans in several directions which plans if heeded will bankrupt the treasury.

The Society is steadily growing in importance and in influence. Its growth and increasing power calls for a larger income. There is no more reason to consider extraordinary expenses than there is justification for an increase in salaries. It is not true that the surplus is unwieldy.

I am very strongly in favor of establishing a sinking fund for future reforms and emergencies. The present, seems to me, an opportune time to establish such a fund. A sinking fund which every Society needs would silence those who favor a lowering of dues and would be an unanswerable argument to those who favor a raise in salaries, finally it would curb extravagance and place the Society in a sound and conservative position.

I therefore *recommend* that this House of Delegates recommend to the Council the setting aside of a sum for the establishment of a sinking fund. If this is done and a budget is carefully worked out, it will be found that neither those who are clamoring for lower dues nor others who are planning extravagances and demanding increased salaries will have any argument on which to base their contentions.

In accordance with the resolutions of the House of Delegates the following special committees have been appointed by the President —

Committee on the Nurses Problem, Committee on Post-Graduate Medical Instruction.

I recommend that the House of Delegates make a careful study of the reports of these committees.

The JOURNAL has steadily improved during the year. Plans are already formed to add a Scientific Department so that in time it will take its place among the best medical journals in the country.

It is with great sorrow that I have to chronicle the death of Dr. W. Dewey Alsever of Syracuse. At the time of his death, Dr. Alsever was Chairman of the Committee on Arrangements and a member of the Council. He was also a past President of the Fifth District Branch. His untiring efforts for both the State and County Societies are well known. I *recommend* that when the House of Delegates adjourns at the evening session it do so in memory of Dr. Alsever.

EDWARD LIVINGSTON HUNT,  
Secretary

April 15, 1925

## REPORT OF THE COUNCIL

### *To the House of Delegates*

The Council of the Medical Society of the State of New York takes pleasure in presenting the following report

In accordance with the By-Laws, the Council has held regular meetings On April 23, 1924, in Rochester, on May 11, 1924, in Albany, and on December 12, 1924, in New York City

A special meeting of the Council was held in New York City on February 18, 1925 At this meeting the Council went on record as approving the Karle-Dunmore Bill, and ordered a referendum vote of the House of Delegates on it The result of this vote showed that 106 members voted in favor of the bill, and 31 against

The Executive Committee has held regular meetings during the year, and a referendum vote of the Council has been taken on all matters of importance, which have come before it

The following reprint received from the Bureau of Legal Medicine and Legislation of the American Medical Association is respectfully referred to the House of Delegates by the Council

### THE REORGANIZATION BILL AGAIN

January 30, Senator Smoot of Utah moved that the Senate proceed to consider the so-called reorganization bill, S 3445, already discussed in the JOURNAL The bill proposed to tear the Public Health Service from its moorings in the Treasury Department and to launch it as a part of a new craft, in a bureau devoted primarily to "education and relief" The motion to take this bill up for enactment in the dying hours of an expiring Congress was defeated The defeat must not be accepted, however, as having put a final quietus on the bill, and another effort will probably be made to obtain consideration If it should pass the House of Representatives, where it is now on the calendar as H R 9629, it may come before the Senate with added prestige A resolution, H Res 395, has already been introduced by Representative Mapes of Michigan, to give the bill the right of way in the House Senator Smoot, in supporting his resolution, charged that "many leading men of the country

who are interested in the public health of the nation are opposed to this measure because of the fact that they have never taken into consideration what the bill proposed to do in relation to the Public Health Service" Unfortunately for Senator Smoot's charge, that is exactly what they have taken into consideration—and that is why they are protesting Senator Smoot in answer to letters objecting to the bill, had stated he said, "just what the bill provides," and then received replies that his correspondents had no objection It would be interesting, of course, to know just what presentation of the case produced such a sudden change of opinion, but it is immaterial If this bill is passed, the meaning of the law must be found within the law itself The Public Health Service, will be removed from the Treasury Department and incorporated in a bureau in the projected Department of Education and Relief No other agency of the government recognizable as a health agency is to be transferred to the new bureau or even to the new department There will be appointed an assistant secretary for public health to look after the affairs of the new bureau That is all the pending bill calls for so far as the public health activities of the government are concerned The proponents of this measure may have intended to write something more into it Unfortunately, that does not help the matter Occult meanings should be made clear, so that all may understand, not merely the fortunate few who were engaged in drafting the bill The criticisms brought against the bill have in no way been met Enactment in its present form may be counted on to delay indefinitely a rational reorganization of public health activities Physicians and all other public spirited persons, individually and as organizations, should at once protest to their Senators and Representatives, against such a miscarriage of legislation Protests already made should be renewed and made stronger

Respectfully submitted,

EDWARD LIVINGSTON HUNT,  
ORRIN SAGE WIGHTMAN,  
GEORGE M FISHER

April 18, 1925

## REPORT OF THE COMMITTEE ON PUBLICATION TO THE EXECUTIVE COMMITTEE OF THE COUNCIL

### JOURNAL

The cost of the JOURNAL to the Society in 1924 was \$21,447 00, an increase of \$14,000 00 This increase is not large when one realizes that during 1924 the JOURNAL was published weekly during the season of the Legislature, making an edition of twenty-one issues instead of only twelve as in 1923

The receipts from advertisements and sales in

the JOURNAL has been about the same as the previous year, the increase in the revenue from these sources for the weekly JOURNAL being only a little over \$1,800 00 in excess of those for the monthly Few of the advertisers care to avail themselves of the weekly publication, most of them prefer to continue as before with only one insertion a month

The JOURNAL was published weekly during the early months of 1925 the same as in 1924 All

papers read at the Annual Meeting of the State Society have been published and the same general policy continued as in 1924

Several new features have been added, among which is a special department, "Medical Surveys" of the different cities and counties of the State

The cost of the JOURNAL to the Society for the year, including the editor's salary, has averaged about \$1,000 00 per issue

Of the 92 advertisers in the JOURNAL, only 8 took advantage of the weekly publication, and 9 others authorized an insertion of their advertisements every other week, leaving 75 advertisers who continued with only one insertion a month. Also, when new advertisements were obtained, in only three instances was the advertiser willing to give a contract for the weekly publication and then for only three or four issues, the others all deciding on monthly insertions

#### DIRECTORY

The Directory was published on time, at a cost to the Society of \$10,000 00. The increase of \$2,000 00 in the cost of publication of the Directory over that of 1923 is due not only to the necessity of publishing a larger edition, owing to the increase in the membership of the State Society, but also to the increase in the size of the book due to the addition of five hundred more practicing physicians in New York, New Jersey and Connecticut, than in 1923. The receipts from advertisements and sales was practically the same as in 1923

It is hoped this year to be able to increase the value of the Directory even more, by again publishing the list of hospitals in the State, as these are of great value to the members of the

Society and were only temporarily omitted owing to war-time conditions

Among the many activities of the Executive Editor which have appeared from time to time in the JOURNAL, are the medical surveys and the reports of the Meetings of the County Societies throughout the State, the data for which he obtains by personally attending the meetings. In regard to the medical surveys the following quoted from the *American Medical Association Bulletin* is an expression of the general appreciation of the work of the Executive Editor, Dr Frank Overton

"For some months the NEW YORK STATE JOURNAL OF MEDICINE has had a department called 'Medical Survey,' to which from two to six pages are devoted in each number. In this department data pertaining to the conditions of medical practice, the number and distribution of physicians, medical societies, hospitals, sanitation, nurses, population, etc, etc, for one or more counties in New York are presented each month

"THE NEW YORK STATE JOURNAL OF MEDICINE is doing a splendid work in making this survey, and in compiling a permanent record of the information thus secured, which is valuable for present purposes as well as for future use. When it is completed for the whole State, the Medical Society of the State of New York will be in possession of facts that every State Medical Association should have about conditions in its own State"

Respectfully submitted,

E. ELIOT HARRIS, *Chairman*,

ORRIN SAGE WIGHTMAN,

EDWARD LIVINGSTON HUNT

April 15, 1925

### REPORT OF THE EXECUTIVE OFFICER

#### To the Council

Your Executive Officer begs leave to offer the following report of his activities since his appointment, November 1, 1924

In accordance with instructions received from the Executive Committee, he immediately set about developing plans that would engender a closer relationship between the County Societies and the State Society. He accepted many invitations, when not prevented by conflict of engagements, to visit County Societies at the time of their meetings and to discuss with them the general subject of "The Relation of a County Society to the State Society." Owing to the fact that many of the County Societies hold their meetings on the same day of the week and month, it was impossible to accept all of the invitations received, nevertheless, in the six months he has been able to attend 19 different County Society meetings, one District Branch meeting, and 5 meetings of other Medical Societies. Of this

number he has had the opportunity of taking a place on 15 programs. He has had several opportunities for addressing lay audiences, which he has accepted

During the first three months of 1925 approximately his entire time was given over to assisting the Committee on Legislation by representing it in the legislative halls of the Capitol. As a lobbyist he devoted most of his time to developing acquaintance and friendship with the legislators and stimulating in them to a high degree the respect and appreciation for the services of the well qualified, conscientious physician, rather than attacking the aims of the ambitious, unqualified representatives of unrecognized cults. His work proved to be very pleasant, for happily he did not find many men lacking in appreciation of the medical man and his profession. Most of them were poorly informed as to the legislative needs of the medical profession and owing to the efforts of those seeking cult legislation, many

had perverted ideas of the aims of the medical profession, as well as a light regard for medical ethics as compared with business ethics. Some of those who were, on first approach, most antagonistic to the desires of the medical profession, later became ardent defenders of its desires. While technically the Medical Society has failed again this year in its effort to secure favorable legislation, it really has advanced its own cause very materially, as was evidenced by the staunch support given by the Assembly to the Department of Education's effort to amend the medical practice act. There is abundant reason to believe that a very satisfactory majority of the Senators were in complete accord with the action taken by the Assembly.

As a member ex-officio of other committees, your Executive Officer has assisted the chairman of the Committee on Scientific Work in developing his program, giving special attention to the preparation of the tuberculosis demonstration for the third day of the annual meeting.

He also met and advised with the special committee on Workman's Compensation Laws, and the chairman of the Committee on Public Health and Medical Education.

In accordance with instruction from the Executive Committee, your Executive Officer took over from the State Department of Health the work it had been doing in locating physicians seeking a practice and supplying localities with physicians where desired. In developing this function as a clearing house, the Executive Officer has relied implicitly upon the advice given him by the Secretaries of the County Societies as to the needs of communities in their jurisdiction.

The functions of the Executive Officer are as yet rather vague and not well defined, but this indefiniteness is not due to a lack, but rather to an abundance of opportunities where immediate work is demanded. His first and prime function is the coordination of the aims and activities of County Societies among themselves and with the State Society. In order to efficiently accomplish this, it seems to the Executive Officer that

*First*—He should be intimately associated with the President of the Society and at all times at his service in the development of his program,

*Second*—He should be ex-officio member of all standing and special committees. He should not take over completely the functions of any committee in the Society, nor the responsibility for any committee's activity, except as he may assist the appointed chairman. Because of his full time service, he can materially aid the chairmen of all committees in constructing a program, securing data and developing its details,

*Third*—He should be the Society's representative at the Capitol during the sessions of the legislature,

*Fourth*—He should visit all County Societies as frequently as possible, making it an aim to visit each Society not less than once in two years,

*Fifth*—He should attend all meetings of the district branches,

*Sixth*—His office should serve as a clearing house for all transactions between the State Society and the County Societies, charitable organizations, the state departments (particularly of health and education), and Societies of other states, by arranging that all communications reach the proper individuals or committees within the Society and by collecting such data as committees may request.

The function of the Executive Officer will eventually, because it is a full time position, so intimately relate itself with every activity of the State Society, that its development should be carefully studied and outlined. Your present Executive Officer appreciates this thoroughly and will most conscientiously and diligently consider every suggested activity before it is undertaken.

Respectfully submitted,

JOSEPH S. LAWRENCE,

April 15, 1925

*Executive Officer*

## REPORT OF COMMITTEE ON ARRANGEMENTS

### *To the House of Delegates*

The Committee on Arrangements submits the following report:

We were very fortunate in obtaining the entire tenth floor of the new Syracuse Hotel for our meeting. This will enable us to have our headquarters and all our meetings in one place.

We have arranged for our banquet to be held on Tuesday evening, May the 12th, and have included an invitation to all the women interested in our meeting. We feel that this will be an advantage in many ways and will afford the wives and ladies attending an enjoyable evening. Dr. Charles W. Flint, Chancellor of Syracuse

University, will address us. Other prominent speakers and entertainers will be present.

The public meeting on Wednesday evening in the ballroom of the Syracuse Hotel will be addressed by Dr. George E. Vincent of the Rockefeller Foundation. This, we believe, will give the society and public a real treat and assures us the success of the public meeting.

We have a very strong Women's Committee under the chairmanship of Mrs. Herman Weiskotten. This committee has made arrangements to provide entertainment for all women attending the meeting. Tuesday afternoon a reception at the home of Chancellor and Mrs. Charles W.

Flint on Walnut Avenue On Wednesday afternoon, automobiles will be provided to give the women a ride through one of central New York's prettiest drives, with luncheon at the famous "Krebs" in Skaneateles

Any members who desire an afternoon at golf

are advised to bring their sticks Arrangements will be made so that they may play on any of the golf links of Syracuse

FREDERICK H. FLAHERTY,  
Chairman.

April 15, 1925

## REPORT OF COMMITTEE ON SCIENTIFIC WORK

### To the House of Delegates

The Committee on Scientific Work reports that they have had two meetings during the year The first meeting was in Albany in November when the outlines of the section-programs were formulated and the second meeting in the Hotel Syracuse, Syracuse, on February 7, 1925, when the programs and all final arrangements for the meetings were completed

The Committee after much consideration has made a decided innovation in the scientific program Thursday, May 14th, has been given over to the complete consideration of tuberculosis in all its protean aspects

At the morning session there will be demonstrations of all phases of this disease pathological and bacteriological, X-ray interpretations and moving pictures of tuberculosis, determinations of physical signs on patients by the stethophone and other methods and the practical value of heliotherapy and the mercury lamp In short everything that the physician desires to know about tuberculosis will be demonstrated

The afternoon session will be given over to fifteen-minute addresses without discussion by outstanding specialists on tuberculosis

It is expected that these two sessions will furnish the most complete presentation of the entire subject of tuberculosis from every standpoint, and will be so valuable and helpful that no live physician can afford to miss them

The Committee has been fortunate in having the assistance of a special committee of which Dr E. R. Baldwin of Saranac Lake, is chairman, in formulating this program

The Committee believes that it would be wise if each section elected its secretary for three years so that there might be harmonious continuity in the sectional work They also recommend that the expenses of program guests from outside of the State be paid also the expenses of laboratory workers, not in practice, from within the State

ANDREW MACFARLANE,  
Chairman.

The recommendations were approved (see page 807)

## REPORT OF THE COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

Societies and the relation of individual members to such work

6 The problem of greater availability of hospitals throughout the State for post graduate teaching

7 The problem of post graduate work for physicians in the smaller centers and county districts

8 Relation of the State to the general question of the scope of medical and pre-medical examinations for persons practicing the healing art, in point of its application to all such acquaintances

and Study of the problems of medical treatment for people in sections of the State too well settled to support a physician  
Propriety of publishing a manual for qualified making health examinations  
His with regrets that this cannot be more than a report of progress, it is respectfully submitted by

JOSHUA M. VAN COTT,  
Chairman

The Reference Committee recommended the of periodic examinations and graduate as major activities (see page 814)

## REPORT OF COMMITTEE ON LEGISLATION

### *To the House of Delegates*

Once more your Committee on Legislation submits its report to you for the year just past

Your Committee has worked assiduously in such measures as have been delegated to it by the Council of the State Society and has attempted to continue the work along the lines originally laid down, together with such variations as have seemed wise, whereby greater interest and activity would be forthcoming from the individual members of the Society as a whole

This year has seen the same conditions maintain in legislative matters in virtually all respects as in the years gone by

There has been a gain, we believe, however, in the enthusiasm shown by the different County Societies and various individuals within the same, which has recompensed your Committee to a very large degree for the efforts demanded of them in their efforts

It has been pleasing to note that many of the adjunct committees have been up and doing, thus bringing credit to the practice of medicine as a whole and to the creation of a greater respect for the medical profession on the part of more and more laymen who have become interested

The various state departments have undoubtedly been in closer touch with the State Society than in years past—a factor sought continuously in our efforts and one which we trust the Society may enjoy upon our successors to continue

While differences of opinion in legislative procedures and questions as to the public good may arise between the Society and some state departments, there is, nevertheless, the unchallengeable fact that personal differences have not entered in and that the questions under consideration have been dealt with purely from a broad viewpoint

A summary of the work is but a compilation of that which has appeared in the JOURNAL during the year and is here appended

1 There were introduced in the Senate 1,474 bills, all of which have been gone over by your Committee on Legislation, and from the number as originally introduced or later amended, 45 bills were followed throughout the course of the legislative session

In the Assembly there were introduced 1,712 bills, and of this number 73 were kept on our lists, though not necessarily actively, until the session adjourned

The usual pernicious bills appeared in the legislature, such as the chiropractic bills of which there were eight different varieties, the antivivisection bill, which died in committee, the Birth Control Bill, several amendments to the Workmen's Compensation Law which of necessity were opposed by your committee

Bills which would have been of benefit to the

interest of public health appeared and were favored by your Committee and their passage worked for But few of these bills were passed The Karle-Dunmore Bill, which provided for more strict regulation of the practice of medicine, unfortunately failed of passage in the closing days of the session through the opposition of Senators George R Fearon of Onondaga County, and Leonard W H Gibbs of Erie County, both of whom were sponsors of cult bills

Assemblyman Charles P Miller of Genesee County, introduced a bill amending the Workmen's Compensation Law by providing for the appointment of a physician as Medical Advisor to be chosen from a list submitted by the Medical Society of the State of New York This bill to a large degree would solve the crux of the conflict which has existed in the labor laws relative to medical attendance, judgment, supervision, advice to the industrial board, examination of fee bills, examining physicians, employment of specialists and the like. Congratulation of this House of Delegates is due Mr Miller for his sound thinking and his attempt to place the burden of the medical features of the board squarely where they belong Unfortunately, this bill failed of passage, but it is hoped that a similar measure will appear early in the next session of the legislature and that the State Society will strongly back such a measure for the benefit of the public

2 It was necessary to draw up, write, and file 12 briefs in opposition to bills presented, and 8 briefs in favor of bills presented in which the State Society took a special interest This did not constitute the entire work in briefing, as it is necessary to arrange the arguments in as few words as possible and in many instances to appear before the various committees and file a brief in duplicate with the Senate and Assembly committees acting on the concurrent bills

3 About 15 hearings were attended by your Executive Officer under the direction of your Committee on Legislation, and filing of briefs which had been drawn up relative to the questions at hand, as well as presenting verbal argumentation, were necessary adjuncts

4 In the matter of correspondence it may be of interest to know the number of pieces of mail handled by your Legislative Bureau From April 15, 1924, to April 1, 1925, approximately 6,000 pieces of first class mail have been sent out, consisting of letters dictated by your Committee on Legislation or by the Executive Officer under the supervision of the Chairman of the Committee on Legislation, in the same time 3,000 pieces of first class mail have been received, and 1,000 pieces of second class, as well as a large number of magazines which were all read and salient articles noted

Early in November, 1924, 60 sets of pamphlets (12 each) were sent to the County Legislative Chairmen, in February, 1925, 200 sets of pamphlets (4 each) were sent to the individual members of the Legislature, four form telegrams were sent to the County Chairmen during the legislative session, and 22 different form letters went out at various times during the year to the County Chairmen, Secretaries and Presidents of County Societies

In a Special Bulletin issued November 7, 1924, we stated that the State Society Journal and the A M A publication "Hygeia" would be sent to influential groups, or citizens, in the various Counties, if the County Legislative Chairmen would but send in their lists. It is interesting to note that we had but two requests for these—one from Clinton County and one from Orange County

Eleven bulletins were issued weekly during the legislative session, beginning on January 17, 1925, and ending on March 28, 1925

With the opening of the session the Legislative Bureau furnished to each officer of the State Society and to the County Legislative Chairmen and Advisory Committee, copies of the Governor's Message, the Clerk's Manual, the Little White Book, and lists of the Standing Committees of the Legislature, to be used for reference during the legislative session. This was done as a matter of courtesy to the individual County Societies, since such information and pamphlets are gladly furnished by each legislator when asked so to do by any one of his constituents. We have, however, been asked for such information by many of our members who do not know the routine of legislation, or who have been averse to exerting themselves to write their own legislators even if they knew them

Whenever bills of extreme interest were introduced sufficient copies of the same were obtained and sent broadcast to each County Chairman, to the Advisory Committee, Council, and officers of the State Society, in order that there might be no misunderstanding in the subject matter when spoken of later

Your Legislative Bureau has also subscribed this year to a press clipping bureau, and over a thousand clippings have been received and perused and notations made of the same for publication in the JOURNAL, or been forwarded to the editorial board of the JOURNAL

5 A large amount of time has been spent by your Chairman of the Committee on Legislation in editing the legislative notes which appeared in the JOURNAL. How many pages of this editorial matter have been put out can be estimated by those who care to enumerate the same in the JOURNAL as they have appeared

Your Chairman has been aided in this matter to no small degree by your Executive Editor of the JOURNAL and the Executive Officer of the

Society, but even with this help there is a vast amount of work which it seems might be handled in some other manner than the taking of time by your Chairman. And yet it is questionable as to who is in better touch with the problems under discussion than your Chairman in conjunction with the Executive Officer

It would seem that the House of Delegates, through its reference committee, could suggest a plan to obviate the large amount of time necessarily spent by your Chairman of the Committee on Legislation in such editorial work.

6 Your Chairman has visited during the year a number of County Societies wherever it was possible for him to devote the time from his personal practice in addition to his other duties pertaining to the Society. This is at great personal sacrifice, but may be said to go with the honor of the position, and in the visitations there is much of social pleasures enjoyed in meeting the physicians throughout the State, which fully repays the time so spent. Your present Chairman of the Committee on Legislation has now conducted the Legislative Bureau for four years and believes that his release should be granted and a successor elected

The Society at large should be pleased to know that no fewer than 10 states are publishing bulletins and medical literature throughout their states and thus instructing their citizens after the pattern of our own legislative bureau

On the 4th of March, the usual Conference of the County Legislative Chairmen and the officers and Council of the State Society was held in Albany—in the planning of which much preliminary work had to be done by your Committee on Legislation and your Executive Officer. That it was a success there is no doubt and your JOURNAL will contain the salient features of what occurred at this meeting

The following officers and members of the Council were present: Drs Owen E Jones, George A Leitner, E Eliot Harris, George M Fisher, Edward Livingston Hunt, Arthur J Bedell, Nelson O Brooks, Harry R Trick, Orrin Sage Wightman, Dr Joseph S Lawrence, Executive Officer, and Dr Frank Overton, Executive Editor of the JOURNAL, and Mr George W Whiteside, Counsel of the State Society

The following members of the Advisory Committee were present: Drs Daniel S Dougherty, Arthur D Jaques, James F Rooney, W Warren Britt, and Homer J Knickerbocker

The following County Legislative Chairmen were present: Drs B E Kinne, Albany County, F H Van Orsdale, Allegany County, E R Cuniffe, Bronx County, H B Marvin, Broome County, H D Chapman, Cayuga County, R H Loomis, Chenango County, R S McDonald, Clinton County, Robert Brittain, Delaware County, J A Card, Dutchess County, G R

Critchlow, Erie County, Peter Noe, Jr, Essex County, John White, Franklin County, Woodard Shaw, Fulton County, J W LeSeur, Genesee County, P G Waller, Greene County, W W Hall, Jefferson County, J A Driscoll, Kings County, P von Zierolshofen, Lewis County, N O Brooks, Madison County, W A Calhan, Monroe County, H Hicks, Montgomery County, Richard Derby, Nassau County, D S Dougherty, New York County, F J Schnell, Niagara County, G M Fisher, Oneida County, H J Knickerbocker, Ontario County, J K Durling, Orleans County, W H Kidder, Oswego County, J C Smith, Otsego County, D J McMahon, Queens County, V G Smith, Richmond County, C D Kline, Rockland County, W J Maby, Saratoga County, H R Bentley, Schoharie County, F W Lester, Seneca County, L M Kysor, Steuben County, W H Ross, Suffolk County, L C Payne, Sullivan County, W A Leonard, Washington County, Ralph Sheldon, Wayne County, C C Sweet, Westchester County, J W LeSeur, representing Wayne County, G H Leader, Yates County

Addresses were delivered at the opening of the Conference by

Owen E Jones, M D, President Medical Society, State of New York

James N Vander Veer, M D, Chairman Committee on Legislation, Medical Society of the State of New York

Joseph S Lawrence, M D, Executive Officer, Medical Society of the State of New York

Dr Augustus S Downing, Assistant Commissioner for Higher Education and Director of Professional Education, University of the State of New York

Matthias Nicoll, Jr, M D, Commissioner of Health, State of New York

William A Howe, M D, State Medical Inspector of Schools, University of the State of New York

Following these addresses an executive session was held and discussion entered into relative to the different bills that were pending, and the following recommendations were made by the Conference relative to legislation

1 That in the proposed County Public Health Nurse Bills, changes be made whereby nurses should not be given the prerogatives of physicians This was adhered to in the legislature and eventually this bill, as amended, became a law in line with the majority thoughts of the Medical Society

2 The Conference went on record as recommending that action on the bill relative to changes in the management of the State Hospital for the Care of Crippled and Deformed Children at West Haverstraw, and the bill making changes in the management of the State Institute for the Study of Malignant Disease at Buffalo, be deferred

until next year by requesting the legislature so to do This was done at the request of a number of members who asked that the proper committees in the State Society study the matter and be prepared to report to the Council or governing body before their introduction next year

3 The Conference went on record as unalterably opposed to the proposition advanced by the State Department of Health, that doctors pay for supplies of antitoxin and the like, in instances where they had neglected to file certain data

4 Quite an amount of discussion was indulged in relative to the various cult bills which had been introduced, and the bill introduced by the State Department of Education, known as the Karle-Dunmore Bill From the tone of the discussion it was very evident that a large majority of the County Chairmen were opposed to all of the cult bills, though a few favored acceptance of the Fearon Bill The Conference, however, went on record as opposed to all cult bills, and in favor of the Karle-Dunmore Bill

5 The following bills which would amend the Workmen's Compensation Law, by providing an injured employee may select his own physician

S Int 380, by Senator Daniel F Farrell, of Kings County, conc A 570, by Assemblyman Gerald F Dunne of Kings County

S Int 594, by Senator Wm L Love of Kings County, conc A 301, by Assemblyman Frank H Lattin, of Orleans County

were then considered by the Conference, and a partial report of the Committee appointed by President Jones, of which Dr J Richard Kevin was Chairman, was read by Dr James E Sadler in Dr Kevin's absence, and contained the thought that it was right and proper for a workman to have free choice of his physician The Conference recommended that the Committee on Legislation take a referendum vote of the County Legislative Chairmen when it seemed advisable

Your Committee on Legislation would ask for instructions from the House of Delegates relative to a bill of this type, particularly as to the thought contained therein

6 The Conference went on record as being in favor of the bill introduced in relation to habit-forming drugs

The Conference adjourned at 1 30 P M and proceeded to the Capitol where the hearing was held on the various cult bills and the medical practice act—a short resume of which will appear in the JOURNAL.

In the judgment of your Committee on Legislation this question will be one of the most important ones at the next session of the legislature and should be carefully considered as to what position the Society will take for the coming year

It must be distinctly understood by the mem-

bers of the Medical Society of the State of New York, that the Committee on Legislation and the various County Legislative Chairmen cannot control the political phase of legislation in such matters, and that many legislators consider the position only from the standpoint of their constituents at home and those from whom they hear

Charity therefore must be accorded to that State Committee on Legislation which happens to be under appointment should a political fiasco occur and cult bills of the same type as those introduced this year be passed

May the day never come when the individual members of the Medical Society of the State of New York agree to a compromise feature or lose the confidence of the majority of the people of the State through the misfortune of the loud cries of an insistent minority overweighing the opposition of the people of the State in the breaking down of the bulwarks so far builded against charlatanism

Much greater enthusiasm has been shown by the Chairmen of the various County Societies in legislative work, yet again some County Societies have seen fit to elect men who have done absolutely no work, as evidenced by the fact that several legislators requested explanations concerning the Karle-Dunmore Bill, and they together with others, made the bold statement that they had not been interviewed by any physicians relative to legislative matters

Many of the communications to the County Legislative Chairmen have been unanswered, and this detracts from the enthusiasm of legislation, when we of the Committee or the Bureau can not get needed information as to how a County Society stands in relation to legislative subjects

It is to be hoped that the Executive Officer may visit these County Societies during this coming year and without fear or favor show them the type of men they have put into office and the disadvantage at which the State officers work, for purely honorary positions, when some parts of the machinery do not function

More County Societies, however, than in previous years have seen the wisdom of sending out small bulletins containing bits of information, not necessarily legislative in character, but all of the efforts of this kind combine to lead up to the ultimate end of education of the people of this State toward what they should demand in public health work

Your Legislative Bureau has been in close touch through correspondence with the Bureau of Legal Medicine and Legislation of the American Medical Association, and it has been a pleasure to realize how much of interest is being taken by the national body relative to the legislative work of this our own Medical Society of this State

Your Legislative Bureau has expended this year some \$6,200 00 which does not equal the budget as passed upon last year, and in the main has stayed within the various appropriations asked for. Of this amount, however, it is estimated that some seven or eight hundred dollars has been expended on behalf of the duties performed by your Executive Officer in the matter of correspondence, telephone calls, extra stenographic services, necessary extra furniture, and so forth, so that once more the expenditures actually chargeable to the Legislative Bureau have not come up to the sum appropriated by your Council. This is no criterion, however, as from year to year the expenditures of such a Bureau must necessarily increase in proportion to the work done, and the time is not far distant when plans must be made for establishing the Bureau on a more firm basis with a regular full time person in charge

Your Committee on Legislation would ask for thoughts from the House of Delegates on this question

It would seem that one of the great efforts of the coming year of your Legislative Bureau or some committee fashioned thereafter, is to reach certain classes of individuals within the State whose consideration of legislative matters and efforts for rightful legislation would be of extreme value

In perusing previous reports of Committees on Legislation the thought has occurred to your present Committee that it would be of the utmost value during the coming summer to have a resumé of legislative effort on the part of the Medical Society indexed and carded for reference, as the subject matter brought forth in legislative and other committee reports to your House of Delegates is now becoming of extreme importance and must needs be correlated for ready reference in order to offset supposed new thoughts which are brought up in succeeding legislatures. At present, a committee on legislation must needs wade through a mass of material in order to ascertain what has been the previous attitude of the State Society or various committees on the same subject throughout the years of our existence

Your Committee on Legislation has been embarrassed in several instances by a lack of unanimity in legislative questions when a majority of the County Societies have been in favor or against certain measures, while a minority group of the County Societies have taken opposite views, and in several instances pressure has been brought to bear on legislators by groups of physicians in affiliation individually or in the whole with the County Society or with the State organization. Your Committee on Legislation asks discussion by the House of Delegates as to how such a condition shall be dealt with,

remembering that the function of the Committee on Legislation is to try and forward or to defeat measures which come up and which are of simple dealings when it knows the sentiment of the Society through the House of Delegates on the bills under discussion.

Your Committee on Legislation would suggest that the House of Delegates tender its thanks to Governor Alfred E. Smith, who has shown by his actions his sane, sincere desire to give to the people of this state the best that could be obtained in the way of public health. This was evidenced by the space devoted in his annual message to the Legislature on questions of public health, and his constant watchfulness and effort throughout the legislative session, and as well should be mentioned his emergency message to the Senate on the last day of the session urging that they report and pass the Karle-Dunmore bill for the better protection of the people of this State. Your Committee on Legislation feels that to him the House of Delegates should accord a communication expressing the sentiment of the Society as a whole.

The appreciation of the State Society is also due Senator John L. Karle, who introduced the State Department of Education Bill amending the Medical Practice Act, and to Assemblyman Russell G. Dunmore, who introduced the companion bill in the Assembly.

It is also suggested that the thanks of this Society be transmitted to Senators Bernard Downing, Nathan Straus, Morton J. Kennedy, Henry G. Schackno, J. Griswold Webb, Ernest G. Cole, Homer A. E. Dick, and to Assemblymen Simon L. Adler, Howard N. Allen, Jerome G. Ambro, Julius S. Berg, Morris Block, John Boyle, Jr., William Breitenbach, John L. Buckley, Frank A. Carlin, Robert A. Catchpole, Edward J. Coughlin, Louis A. Cuvillier, F. Trubee Davison, Daniel L. Dayton, Owen J. Dever, Edward J. Donohue, Russell G. Dunmore, Gerald F. Dunne, Nicholas J. Eberhard, Marcellus H. Evans, Clarence L. Fisher, Frank R. Galgano, Alexander H. Garnjost, Joseph H. Gavan, Abraham Grenthal, Delbert C. Hall, Lewis F. Harder, John P. Hayes, J. Murray Hearn, John J. Howard, Henry W. Hutt, Adolf F. Johnson, Paul T. Kammerer, Jr., Joseph E. Kinsley, J. Maxwell Knapp, Mark T. Lambert, Frank H. Lattin, Frederick B. Linen, Ralph H. Loomis, Bert Lord, Thomas J. McDonald, John J. Meegan, Charles P. Miller, Frank A. Miller, John P. Nugent, Lester W. Patterson, John F. Reidy, Michael J. Reilly, Joseph F. Ricca, James R. Robinson, Frederick J. Slater, Frank M. Smith, Lewis G. Stapley, William D. Thomas, Richard D. Tonry, Morris Weinfeld, William Wickham, John R. Yale, to these men we, as physicians, are indebted for their sound thinking, wise counsel and staunch support or opposition in such measures of public health which your

State Society has deemed to be of value to, or detrimental to the citizens of the State. Were it not for these men who patiently listened and then had the courage to act, this State of New York might be in the same position as many states now are where political opportunities have been seized upon to the detriment of the people of those states. We undoubtedly have overlooked some—but it is of the pen unwittingly and not of the mind.

We desire at this point to speak of the cordiality of the individual legislators especially, and in fact of the majority of those with whom we have come in contact personally or through correspondence. Your Executive Officer will speak of this at greater length, but your Committee on Legislation desires to make mention of that fact here.

It would be amiss as well not to mention those legislators who, for reasons known only to themselves have, in the minds of your medical thinkers, lost their sense of perspective and have voted or worked for the destruction by legislation of our medical laws, our State Department of Health, our State Department of Education, our State Hospital system, as well as the individual governmental functions of local boards and institutions. These men who have though their support of legislative matters along such lines would be of more worth to the State have been Senators Arthur F. Bouton, George R. Fearon, Leonard W. H. Gibbs, Edmund B. Jenks—but from the standpoint of the Medical Society their position most certainly can be questioned by the majority or their constituents.

#### RECOMMENDATIONS

Your Committee on Legislation recommends to the House of Delegates of the Medical Society of the State of New York, for their action, the following:

- 1 That the Legislative Bureau be continued, and a sufficient appropriation, under a budget system to be offered by the new Chairman of the Committee on Legislation, be allowed.
- 2 That provision be made for one or more conferences of County Legislative Chairmen, as in the past.
- 3 That some provision be made whereby your Committee on Legislation may co-operate with physicians who have grouped themselves into special societies, usually with community interest, some of whose members are not members of the State Society, in legislative matters. I believe this will be spoken of in another report, but your committee on Legislation would recommend that the proper changes be made in our constitution and by-laws for some type of legislative representation of such societies.

- 4 That your Executive Editor be directed to come to Albany during the legislative session and spend one or more days in Albany each week at the expense of the Society, thus becoming more familiar with legislative matters and being able the more to edit legislative articles for the benefit of the JOURNAL
- 5 As before, we again recommend a broad dissemination of education on public health questions through the public press by means of someone of the adjunct committees of the State Society—thus laying a better foundation for the legislation which may come up, and would respectfully suggest
  - (a) That the JOURNAL of the State Society be sent during the legislative session to all the legislators, to the newspapers published in this State, to the officers and members of the Executive Committees of the allied professions, State or District Societies of nurses, dentists, school medical inspectors, health officers' associations and the like, and to a selected group of lay societies
  - (b) That conferences be held in the Council of the Society as to certain other selected medical and educative publications which should be sent to these groups

Several of these recommendations were favorably passed upon last year by the House of Delegates, but unfortunately your Executive Committee negated the will of the House of Delegates and as a result the JOURNAL of the State Society did not reach the legislators except in a few instances where it was specifically asked that it be sent. This was not called to the attention of your Chairman or the Committee on Legislation, and under the impression that the JOURNAL was being sent to the legislators, many of the articles written by the Chairman were so phrased as to show the legislators that the physicians of the State had nothing to hide, but were sending these Journals to them in order that they might be read and the legislators inform themselves as to the viewpoint of physicians in relation to much of the matter under discussion

- 6 We would again recommend that the same rule be adopted in relation to physicians—members of the State Society—appearing before committees of the legislature without first consulting with the Chairman of the Committee on Legislation

It has been intimated that such a recommendation tends to stifle certain criticisms, but we have yet to hear of a single physician being refused introduction on the part of the Committee on Legislation when he has asked honestly to be so presented. There have been present, however, at a number of committee hearings, members of the State Society who probably were unaware of the

rule, but who have caused some inconvenience to your committee, in that a legislator who might wish to indulge in sharp practice could easily point out that the members of the medical profession were woefully divided on important questions of the day whereas the individual physician so appearing might be only giving his personal views, and under this rule would be forbidden to boldly state that he was appearing for a recognized group of physicians when such was not the case, or when such a group did not exist

In this connection it is recommended that the Secretary of the Medical Society of the State of New York be directed to write any physician who so appears before a committee and to officially call his attention to the action of the State Society in relation to this rule

- 7 That the County Societies be urged to meet with their legislators in the fall or at some convenient time in a social way and that it be obligatory on the Council Society to so report to the Council or Committee on Legislation, since much good has come from the meetings so held by many County Societies but, unfortunately, the reports of such meetings only reach the Legislative Bureau in a roundabout manner
- 8 That legislation which is sought by County Societies and individual members be sent in to the Bureau in the early fall, so that the Counsel of the Society may draw up in proper form such legislation and submit it to the Council and Committee on Legislation before the opening of the session, and that any legislative suggestion or thought within or by a County Society shall be in the hands of the Council for approval or disapproval not later than September 1st, 1925
- 9 That the Council of the Society be directed to form some type of Advisory Committee of the profession of this State which shall eventually become an Advisory Council to governmental officers or departments when advice is so sought, since in many instances some physicians in private meetings with legislators hold themselves out to be representatives of many of these bodies and would convey to the individual legislators the thought of their importance of position, thus negating the efforts of the duly accredited officers of the various and individual professional societies. This does not work for a harmonious entity in matters of public health legislation, but by such a movement a body would be created which can speak with authority in allied matters of public health from all angles pertaining to the people of this State

- 10 That the position of the State Society in relation to legislation as it may appear in the legislature be the same on such similar matters as has maintained in the past years unless a specific resolution be passed by the House of Delegates, by referendum vote, or by the Council, thus changing the position of the Society without placing the burden of such change alone on the Committee on Legislation.
- 11 That legislation which has come up in the past session in reference to the State Institute for the Study of Malignant Disease at Buffalo, and the State Hospital for Crippled and Deformed Children at West Haverstraw, be referred by this House of Delegates to the proper committee of the Society for study and suggestions as to action for your next Committee on Legislation. The same report to be given to the Council by September 1st, 1925, that they may act upon it for the guidance of the Committee on Legislation
- 12 That this House of Delegates discuss the old and familiar bills as to Birth Control, Anti-vivisection, Child Experimentation, amendments to the Medical Practice Act, and place on the records of the House of Delegates what action shall be taken by the Committee on Legislation during the coming year so far as can be determined in the light of past legislation
- 13 That this House of Delegates go on record as favoring a bill similar to Assemblyman Charles P. Miller's bill, A. Int. 1351, and direct your Committee on Legislation to confer with the County Legislative Chairmen and legislators urging the passage of the same or some similar measure
- 14 That this House of Delegates approve or disapprove of the wording and legislative thought contained in the Kennedy-Weinfeld bill concerning habit-forming drugs
- 15 That this House of Delegates record itself as for or against the free choice of physician by an injured workman
- 16 That the Committee which was appointed to study the Workmen's Compensation Law be continued or a similar committee be appointed, and that they be directed to place in the hands of the Council their recommendations for amendments to the Workmen's Compensation Law in relation to the medical features thereof by September 1st, 1925, in order that the Council may draft the proper bills for introduction, and submit them to the Council by the 1st of December, 1925, should the Council pass favorably upon their introduction
- 17 That any legislative suggestion or thought within or by a County Society shall be in the hands of the Council for approval or disapproval not later than September 1st, 1925
- 18 That the House of Delegates direct that the services of the Executive Officer shall be wholly under the direction of the Committee on Legislation from the 1st day of December until one month after the closing of the legislative session
- 19 That some means be devised whereby articles on medical topics may be syndicated to newspapers through the editorial office of the JOURNAL or a Press Bureau to be established within one of the standing committees of the Society, from whence can be sent to newspapers, lay organizations, churches, schools and the like, authentic and interesting articles concerning the public health and the duty of the individual in relation to the health of his neighbor. This is one of the crying needs of the Society at the present time and it might be of advantage to the Society were some journalist engaged upon half or full time to help the committee upon whom such work would fall

Respectfully submitted,

JAMES N. VANDER VEER, *Chairman*,  
GEORGE R. CRITCHLOW,  
WALTER H. CONLEY

## REPORT OF COMMITTEE ON MEDICAL RESEARCH

*To the House of Delegates*

Your Committee has functioned by gathering data and preparing to oppose the usual attempts to interfere, by legislation, with the necessary and orderly scientific experimentation on animals as at present conducted by properly authorized Medical Schools

An amendment to the Penal Code of the State was introduced in the Legislature which, if passed, would prohibit any investigations or experiments on living dogs

This amendment, owing to the accumulation of other matters, was not reported out of committee and as no hearing was called on the bill, your Committee did not find it necessary to appear at Albany

Respectfully submitted,

W. MORTIMER BROWN,  
*Chairman*

April 15, 1925

4 That your Executive Editor be directed to come to Albany during the legislative session and spend one or more days in Albany each week at the expense of the Society, thus becoming more familiar with legislative matters and being able the more to edit legislative articles for the benefit of the JOURNAL

5 As before, we again recommend a broad dissemination of education on public health questions through the public press by means of someone of the adjunct committees of the State Society—thus laying a better foundation for the legislation which may come up, and would respectfully suggest

(a) That the JOURNAL of the State Society be sent during the legislative session to all the legislators, to the newspapers published in this State, to the officers and members of the Executive Committees of the allied professions, State or District Societies of nurses, dentists, school medical inspectors, health officers' associations and the like, and to a selected group of lay societies

(b) That conferences be held in the Council of the Society as to certain other selected medical and educative publications which should be sent to these groups

Several of these recommendations were favorably passed upon last year by the House of Delegates, but unfortunately your Executive Committee negated the will of the House of Delegates and as a result the JOURNAL of the State Society did not reach the legislators except in a few instances where it was specifically asked that it be sent. This was not called to the attention of your Chairman or the Committee on Legislation, and under the impression that the JOURNAL was being sent to the legislators, many of the articles written by the Chairman were so phrased as to show the legislators that the physicians of the State had nothing to hide, but were sending these Journals to them in order that they might be read and the legislators inform themselves as to the viewpoint of physicians in relation to much of the matter under discussion

6 We would again recommend that the same rule be adopted in relation to physicians—members of the State Society—appearing before committees of the legislature without first consulting with the Chairman of the Committee on Legislation

It has been intimated that such a recommendation tends to stifle certain criticisms, but we have yet to hear of a single physician being refused introduction on the part of the Committee on Legislation when he has asked honestly to be so presented. There have been present, however, at a number of committee hearings, members of the State Society who probably were unaware of the

rule, but who have caused some inconvenience to your committee, in that a legislator who might wish to indulge in sharp practice could easily point out that the members of the medical profession were woefully divided on important questions of the day whereas the individual physician so appearing might be only giving his personal views, and under this rule would be forbidden to boldly state that he was appearing for a recognized group of physicians when such was not the case, or when such a group did not exist

In this connection it is recommended that the Secretary of the Medical Society of the State of New York be directed to write any physician who so appears before a committee and to officially call his attention to the action of the State Society in relation to this rule

7 That the County Societies be urged to meet with their legislators in the fall or at some convenient time in a social way and that it be obligatory on the Council Society to so report to the Council or Committee on Legislation, since much good has come from the meetings so held by many County Societies but, unfortunately, the reports of such meetings only reach the Legislative Bureau in a roundabout manner

8 That legislation which is sought by County Societies and individual members be sent in to the Bureau in the early fall, so that the Counsel of the Society may draw up in proper form such legislation and submit it to the Council and Committee on Legislation before the opening of the session, and that any legislative suggestion or thought within or by a County Society shall be in the hands of the Council for approval or disapproval not later than September 1st, 1925

9 That the Council of the Society be directed to form some type of Advisory Committee of the profession of this State which shall eventually become an Advisory Council to governmental officers or departments when advice is so sought, since in many instances some physicians in private meetings with legislators hold themselves out to be representatives of many of these bodies and would convey to the individual legislators the thought of their importance of position, thus negating the efforts of the duly accredited officers of the various and individual professional societies. This does not work for a harmonious entity in matters of public health legislation, but by such a movement a body would be created which can speak with authority in allied matters of public health from all angles pertaining to the people of this State

- 10 That the position of the State Society in relation to legislation as it may appear in the legislature be the same on such similar matters as has maintained in the past years unless a specific resolution be passed by the House of Delegates, by referendum vote, or by the Council, thus changing the position of the Society without placing the burden of such change alone on the Committee on Legislation
- 11 That legislation which has come up in the past session in reference to the State Institute for the Study of Malignant Disease at Buffalo, and the State Hospital for Crippled and Deformed Children at West Haverstraw, be referred by this House of Delegates to the proper committee of the Society for study and suggestions as to action for your next Committee on Legislation. The same report to be given to the Council by September 1st, 1925, that they may act upon it for the guidance of the Committee on Legislation.
- 12 That this House of Delegates discuss the old and familiar bills as to Birth Control, Anti-vivisection, Child Experimentation, amendments to the Medical Practice Act, and place on the records of the House of Delegates what action shall be taken by the Committee on Legislation during the coming year so far as can be determined in the light of past legislation

## REPORT OF COMMITTEE ON NURSE PROBLEM

### *To the House of Delegates*

At the annual meeting of the House of Delegates held at Rochester in 1924 the following Resolution was presented

Dr Critchlow, Erie I wish to present the following resolution, passed by the Society of the County of Erie

WHEREAS, Deplorable conditions have developed and now obtain in an ever increasing degree in the relations existing between the group of Registered Nurses on the one hand, the physicians and the general public on the other, and

WHEREAS, We feel that the laws of the State of New York now governing the training of nurses are serving to educate a group of women beyond the point of practical usefulness in the actual care of the sick, and

WHEREAS, A large percentage of such highly educated nurses elect to follow the work of public health nursing, institutional instruction and other lines of work than actual nursing of the sick, and

WHEREAS, We feel that the lines of work just mentioned do perhaps require education and training of the kind now conducted in our registered schools, but

INASMUCH as there is a crying need for a group of women who shall be trained in the practical duties pertaining to a real nurse, and who shall be thoroughly imbued with the idea that the first and greatest function of a nurse is to care for the sick, and

INASMUCH as it is generally agreed by the medical profession throughout the country that women may be properly and thoroughly trained for such duties in a much shorter time than is now required for the graduation of Registered Nurses, and that a curriculum requiring less theoretical teaching and more bedside training can be adopted that would develop efficient nurses in from nine months to a year, and

INASMUCH as such hospitals as attempt to carry out such a course of instruction are hampered in their work by opposition from the Department of Education, now, therefore, be it

*Resolved*, That the delegates of the Medical Society of the County of Erie be and hereby are instructed to bring this matter before the House of Delegates at its annual meeting in the City of Rochester on April 21st, 1924, and urge upon that body the advisability of the Medical Society of the State of New York as a body attacking this problem and supporting, by every means in its power, legislation looking toward an amelioration of the conditions now existing

This was referred to Reference Committee B which reported as follows

Dr Sadlier In relation to the resolution introduced by Erie County, through Dr Critchlow, with reference to the question of the nursing situation, we believe that the first four paragraphs of the resolution are in accordance with the ideas of the medical profession in general. We disagree with part of the sixth paragraph, and would suggest that you introduce after "registered nurse" the following "In order to meet the demands of suffering humanity and at the same time not interfere too radically with the present teaching of pupil nurses, we suggest that the preliminary educational requirements for entrance into training schools be modified so as to make graduates of eighth grade eligible for acceptance in the training schools of the State, and that the required course of instruction throughout the State be reduced to two years, with a lessened amount of theoretical teaching and a more intense course of bedside training"

We disagree with the sixth paragraph, in so far as it

asserts that efficient nurses could be developed in from nine to twelve months, and feel that this type of nurse is cared for by provisions of the law in reference to trained attendants

We recommend that the President of the State Medical Society appoint a committee of three to confer with the Department of Education with a view to legislation along the lines suggested by this resolution of Erie County and revised by this Reference Committee.

The House of Delegates adopted this report and a Committee was duly appointed by the President

The Committee has sought information on this topic from various sources to enable it to discuss the matter intelligently with the State Education Department We carefully studied the present Nurse Law of the State of New York, also all available published reports and statistics This was supplemented by correspondence and interviews with many physicians, nurses and superintendents of Nurse Training Schools Finally we held lengthy conferences with the proper authorities in the State Education Department From every source it was admitted that the general situation was not entirely satisfactory We also ascertained that the problem of the trained nurse, especially in her relations to the public and the profession, is not confined to New York State alone, but is exciting serious attention generally throughout the United States in many parts of which, not nearly so high requirements and standards obtain

A brief retrospect of the progress of Nurse Education in New York State shows that prior to 1903, there was no standard curriculum The degrees of discipline and thoroughness of training varied widely and were dependent upon the particular kind and amount of clinical experience each individual hospital provided, and upon the ideals, initiative and character of the superintendent of nurses

At that time several Correspondence Schools of Nursing flourished and produced many "graduates" who were allowed to practice as trained nurses There was no law to prevent this A number of hospitals, not all of them small ones, maintained training schools in name only, furnishing the most mediocre courses of instruction and oftentimes an unbalanced clinical experience Too frequently the young women were exploited Under the guise of disciplinary training, they were required to do a large share of the housework of the wards Many were improperly housed and cared for, and subjected to prolonged and exhausting hours on duty

The prevalence of these abuses prompted a demand for reform by intelligent groups of physicians, nurses and educators In 1903, a Nurse Law was passed designed to regulate the training of the Nurse and to place her calling on a dignified plane The State Education Department

was authorized to prepare a curriculum and such necessary rules and regulations, as might be required under the circumstances, to ensure adequate education, bedside experience, and proper living conditions to protect the health and morals of the nurse in training. These were compiled and adopted only after careful and conscientious study by a committee of physicians, trained nurses and representatives of incorporated hospitals who advised the Department on the questions involved.

Whatever provisions were instituted, as a direct result of this law, were made to apply so gradually as not to disturb too abruptly the existing order of things or methods of training, then in vogue, in the better class of hospitals. Liberal concessions and extensions of time were granted to many hospitals which, for good and sufficient reasons, were physically unable to comply at once with the necessary requirements.

A waiver clause was provided to fully protect the rights of all nurses then actually in practice. For several years following the passage of this law, there were no restrictions on the use of the term *Trained Nurse*, provided the nurse had graduated from a hospital training school. The acquiring of an *R N* degree by State examinations was purely optional until 1920, when an amendment to the law was enacted, which restricted the use of the titles "trained, certified, graduate or registered nurse" to those who were graduates of Training Schools registered by the Education Department, and had passed the Nurse Examination Board. However, a waiver was in force until January 1923 to enable any nurse to register who had actually carried on nursing for the previous five years in this State. This allowed even practical nurses of experience to register. There was manifest a very liberal spirit on the part of the Education Department to allow ample time and opportunity for registration and readjustment.

At no time in the past or at present has any person been prevented by this law from engaging in nurse practice. The registration of schools of nursing is not compulsory, but since 1920, only graduates of schools approved by the Education Department are eligible for entrance to the licensing examinations. In short, the Department concerns itself solely with such schools and graduates as voluntarily elect to comply with the rules governing State registration. There is nothing in the law to prevent hospitals conducting training schools in any manner they see fit. However, such institutions cannot receive the official approval of the Department unless certain minimum standards are maintained. Obviously, when not maintained, the graduates of such are presumably of inferior training and cannot apply to themselves the specific terms "trained, certified, graduate or registered nurse," as these terms are

now, by law, an indication of having had a definite degree of general education, hospital training and bedside experience of a uniform quality and quantity throughout the entire State.

From time to time, as conditions appeared to warrant, the curriculum, prescribed by the State Education Department, has been modified. The alternative of three courses is allowed. One of two years training, one of two years and four months, and one of three years. The same amount of theory is required in all three types. The chief advantage of the longer course being that the work is more distributed and opportunity provided for a broader culture and study in advanced subjects from the optional group. In any of the courses, the total number of hours of didactic or theoretical instruction is about four hundred which would be approximately 7 per cent of the time in the case of a two years and four months course, thus allowing 93 per cent of the time for bedside practice. This does not take into consideration the four hours a week which the nurse should devote to study in her room or the study hall when off duty.

The Department requires of all registered schools an adequate course of nursing experience in surgery, obstetrics, medicine, pediatrics, dietetics and massage. Whenever the hospital cannot provide sufficient practical experience in one or more of these branches, the student must be sent to an approved hospital where she can gain this experience. This matter of affiliation presents certain difficulties. To leave one school and enter another temporarily is a serious interruption, but if we are to give the nurses a comprehensive training and practical experience in all branches, it appears to be the only method of procedure when the hospital is other than a general one, well supplied with clinical material of all kinds.

The Education Department is absolutely correct in this matter. Much of the criticism and complaint of the Department's "hampering methods" has emanated from the hospitals which were loath to affiliate their students with other hospitals for needed experience. The very element of training now so strenuously advocated—practical bedside experience, is just what the Department has found its greatest difficulty in securing for the pupil nurse in a great many instances.

According to the present syllabus which is now being revised, theoretical instruction is required in the following subjects

- 1 Nursing Principles and Methods
- 2 Anatomy and Physiology
- 3 Bacteriology
- 4 Nutrition and Cookery
- 5 Hygiene, Public Sanitation
- 6 Materia Medica

7 Nursing in Medical Diseases (including communicable diseases)

8 Nursing in Surgical Diseases (including operating room technic and gynecological nursing)

9 Obstetric Nursing

10 Nursing of Children

11 Nursing in Nervous and Mental Diseases

In all, approximately 400 hours time of lectures and classroom

The State Board Examinations are based upon the assumption that all candidates have been satisfactorily instructed in the subjects above enumerated

The minimum educational requirement to enter an approved school is one year of high school or its equivalent

143 Hospital Training Schools are now registered with the Education Department as approved schools. In 1914 there were 3,976 students training in approved schools, while in 1924 there were 5,246—an increase of 31 per cent. In this same period the increase of occupied beds in the hospitals was 29 per cent.

Over a recent period of twelve months, 767 pupil nurses left training for various reasons. Fifty-six per cent of these left on account of dislike of work, incompetence, not fitted for work, unable to carry theory, and misconduct. The percentage of those unable to carry theory was slightly under 9 per cent of all who left school. However, 90 per cent of those who left from this cause were admitted to the schools on only one year of high school or its equivalent.

There are now eighteen Hospital Training Schools in the State not registered. There are eight Registered Schools for training "Attendants." It is estimated that 1,000 pupils are training in non-registered schools. Of this number, the larger share is in the State Hospital group.

Since 1903 the Department has issued a total of 43,903 registered nurse certificates of which about 25,000 were granted through examinations. Over 17,000 were issued between 1920 and 1923 under the waiver clause. Included in the above are 8,346 graduate nurses from other states. In addition, the Department has issued 1,462 certificates to graduates of the State Hospital Schools for the care of the insane.

From the above figures it is readily seen that a generous proportion of nurses, now in actual practice, are *not* the product or end result of the training required by the Department, but are holding the R. N. certificate through the waiver clause demanded for those who became nurses before 1920. This fact deserves special emphasis when discussing the present program of supervision of registered nurse training. Manifestly, the Department cannot be condemned for the character and general attitude of registered

nurses who were educated and trained outside its domain.

The specific duty imposed upon this committee was to confer with the Department of Education with a view to legislation along the lines suggested by resolution of Erie County and revised by the Reference Committee. We are able to report that such conferences were held and that the attitude of the Department was one of willingness to confer with authorized committees of the Medical Society of the State of New York for the purpose of modifying any part of the curriculum when such seemed best for the promotion of nurse training and establishing better relations between the nurse and the Medical profession.

We ascertained that all of the suggestions contained in both the resolution and the Reference Committee report could be carried out, if wise, without resorting to legislative act. The present law appears to be sufficiently elastic to permit this.

Whatever differences may now exist between the Education Department and certain groups of physicians are purely due to a wide variance of ideals and opinions as to the status of the trained nurse.

When the Department established a definite curriculum designed to give adequate education and practical bedside training to create a trained nurse, it made at the same time ample provision for the training of young women to be known as Trained Attendants. The amount of training of this latter group corresponds very closely to that proposed as an abbreviated course in the original Resolution and Reference Committee report. As a matter of fact, it is possible for any hospital, at the present time, to conduct this short course of training without any unreasonable restrictions from the Department. However, the graduates of these will not be allowed to sail under false colors by calling themselves anything else than "Trained Attendants" or "Nurse," as they have not had sufficient education or experience to warrant being called by any other name.

The matter of employing a descriptive title should always take into consideration the accepted meaning of the words from long usage in our language. Such terms as trained, certified or graduate nurse imply and suggest thorough training, efficiency, dependability and knowledge born of theory correlated with experience. In a recent bulletin of the Erie County Society an entirely new set of technical terms was suggested, viz "qualified nurse," with a privilege of using the degree "Registered Qualified Nurse," and "master nurse," with the privilege of using the degree of "Registered Master Nurse." Each of these degrees to indicate a specified amount of training and varying proportions of theory and practice. The chief criticisms of this nomen-

clature are that they are entirely new and untried terms, without equivalent in other states, and that the public would be unable to comprehend their technical significance or differential values. To add these new terms to the category would only serve to further confuse and perplex.

It is the opinion of this committee that the accepted uses of the words "trained," "certified," "graduate," and "registered" nurse should be continued as in the past to indicate a certain type of intelligent woman, capable of attending the sick and co-operating with the attending physician, and that the words "trained attendant" should stand for a woman who has had a relatively briefer course, principally confined to bedside service.

We believe there are grounds for honest differences of opinion as to the amount of so-called theory to be included in the instruction of the trained nurse.

From the State Education Department we ascertained that its idea of including in the curriculum the amount of theoretical instruction now prescribed (only 7 per cent of the total time) is that the public has a right to expect the nurse to know something of *why* as well as *how* to carry out nursing procedures, observe symptoms and appreciate their significance.

After a careful survey of the various subjects included in the theoretical instruction, we feel that none could be entirely omitted, but that it would be desirable to modify the amount and degree of some. A perusal of the suggested and required textbooks shows beyond all doubt that the nurses are now required to study from essentially advanced scientific works, far beyond the practical needs of a trained nurse and of such a character that, to properly assimilate them would require entirely too much time and energy of the student. We believe the ends to be obtained in educating the nurse could be accomplished by more simplified forms. We received assurances from the Education Department that this important matter would be given careful consideration during the process of revision of the syllabus and that advice from a committee of the State Society would be welcomed and desired.

After reading several examination question papers submitted to the nurses by the State, the committee believes the general character of these should be more practical. It was suggested that physicians should edit these questions, but this is not the unanimous opinion of the committee. It should be borne in mind, however, that the physicians, themselves, as lecturers to the nurses have a definite responsibility in the selection and character of the instruction, and ought to be consulted, in an advisory capacity at least, concerning the questions to be asked.

We do not consider from our investigations that the present curriculum overeducates the nurse in the theoretical part, to such an extent that

she is useless in the sick room. As already stated, 93 per cent of her time is devoted to bedside training and experience. The Education Department insists that this shall be comprehensive and shall include actual nursing experience in surgery, internal medicine, pediatrics, obstetrics, dietetics and massage. It is not logical to say that an intelligent woman, drilled in these for the better part of two years will leave the training school unfit for service in the sick room.

There is not a physician who reads this report but would, in case of personal illness or sickness in his own family, select a registered trained nurse in preference to one of less training.

We do not agree that the present standard of education and training is responsible for a large proportion of registered nurses deserting the sick room for Public Health and Institutional teaching. According to a committee report of the Philadelphia County Medical Society, only about 15 per cent so elect. The real reason is that these activities offer distinct advantages such as definite and shorter hours, steady and assured income, and a certain degree of independence which every normal person craves. We fail to understand how any amount of training in the practical duties of a "real nurse" will imbue her with the idea that "the first and greatest function of a nurse is to care for the sick." No amount of moral suasion can overcome the practical fact that Public Health and Institutional service have very attractive features not possessed by plain nursing of the sick. As regards the depletion of nurse supply by these agencies, it must not be overlooked that they are of distinct economic value to the community, in that they reduce greatly the incidence of illness and infection which, if not prevented, would add infinitely to the general nursing requirements.

Possibly one of the most important topics brought to our attention by Reference Committee B was that referring to preliminary educational requirements for entrance into training schools. It was suggested that graduates of the 8th grade should be eligible for acceptance in the nurse training schools.

We are convinced that this would be unwise. It is manifestly unfair to admit young women into the nursing profession today who have not the necessary background of education to give them a fair chance of grasping the problems which they are undertaking. In view of the fact that high school advantages are available for nearly all today, whether living in towns or country, one may well inquire, do we want girls as nurses who are so devoid of ambition as to rest content with the limitations of the eighth grade which is usually attained at the age of 13 or 14? Statistics from the State Education Department are very enlightening on this topic. During the past four years 45 per cent of the students entering the approved training schools had from two

to four years of high-school instruction, and 90 per cent of the number of students leaving the schools because they were unable to carry the theoretical work were those admitted on a one year of high school or its equivalent

No one can appreciate the advantages of a good fundamental education better than the superintendents of nurses. They will invariably prefer a high school graduate if obtainable.

We all recognize that education has civilized the world and lifted us from barbarism. Generally speaking, it is commendable for all walks of life. This is particularly true of nursing.

This committee is unalterably opposed to lowering the standards of preliminary educational requirements. We are strongly in favor of raising the present requirements to at least two years high school and preferably a full high school course.

In this connection, it has recently been advocated to provide a preliminary course to nursing in our high schools—one including anatomy, physiology and hygiene, chemistry, home economics and such other subjects useful in a nurse's life. Once this course became generally established, the burden of education in these branches would be lifted from the hospitals. Furthermore it would serve to retain the attention and interest of prospective candidates for nurse training during the period between grammar school and the age of 18 when they first enter the hospital for training. We recommend that this project receive serious consideration by the Society.

The first paragraph of the resolution states "Deplorable conditions now obtain in the relations between the group of registered nurses on the one hand, the physicians and the general public on the other." With what follows, the purport is that the State of New York, through its Department of Education, is largely responsible for this situation on account of the high standards exacted of the schools of nurse training. It is implied that this training produces a super-nurse totally unfitted and unwilling to care for the sick. The suggested remedy is to substitute the present system by one which takes girls whose education terminated at fourteen years of age, and makes efficient nurses of them in a period of nine months to a year. Relative to this, a prominent member of Erie County has stated in a published article, "Any intelligent girl can be taught the proper nursing care of the sick in a year's time." If such were humanly possible, the committee feels it would be the most happy solution of the problem. We would again remind such, as advocate this or similar plans, that there is nothing in the present law to prevent them from making the experiment. We have assurances from the Education Department that there would be no official interference.

The committee cannot subscribe to the idea

that higher education is largely responsible for the "deplorable conditions" which we interpret to mean, the twelve hour schedule, scarcity of nurses, exorbitant fees, unwillingness to do domiciliary nursing, and selective choice of cases. To all of which might be added "the apparent growth of the mind on the part of many nurses to exercise the functions of a physician rather than a nurse." That these faults sometimes do exist must be admitted, but a critical analysis of them shows conclusively they are purely economic in origin rather than due to cultural influences.

The same complaint is heard from all parts of the country, regardless of educational restrictions. We do not believe the problem can be readily solved by quantity production of cheap nurses, that is, nurses of inferior education and limited training.

The present demand for nurses is tremendous, arising partly from necessity, but in no mean proportion from one of our greatest national faults, a love of luxury. The absorption of the supply of nurses by the rich, and too often by those who can ill afford it, when their cases do not require a "special" is a common event in hospital practice. Under the present system of exclusive use of a nurse's whole time by an individual case, it is doubtful if it were ever possible to fully satisfy the demand. A more intelligent and efficient disposal of our present supply of nurses would go far toward solving the problem of dearth. This can be accomplished, partly at least, by group nursing and by the medical profession frowning upon the use of valuable nurses on simple and uncomplicated cases. The employment of trained attendants in this type of cases should be encouraged.

The great increase of fees appears to be noted chiefly in the larger cities where there are greater demands for nurses and a larger wealthy class willing to pay the price when necessity arises. These two factors determine the price of everything. The ability to get the price plus the increased cost of living have prompted the nurse, like all other personal service groups, to raise the fees. At this point we desire to call attention to the methods of the commercial nurse registries. They derive their income by collecting a percentage of the first week's fees of the nurse. Needless to add they do not encourage moderate fees or long hours. By utilizing this type of nurse registry, the medical man has unwittingly fostered a vicious system. Many of these refuse to submit the qualifications of the nurses they supply, and it is known that they send incompetent and unregistered nurses who have no legal right to assume the name of trained nurse.

The hospital or professional nurse registries send only trained nurses or trained attendants as such, and in some instances, send practical

nurses but properly labeled. They charge only a nominal fee annually and endeavor to exert a proper influence over their registrants as regards reasonable fees and service

Bearing on this topic, we refer to the recommendations adopted by the New York State Nurses' Association

(a) That professional registries change their names to that of Official Registry

(b) That where there are two or more registries in a community, they combine to form one central registry

(c) That the central registries register and send out for employment licensed nurses, trained nurses (State Hospital graduates) trained attendants, and practical nurses, all groups to be controlled by certain rules and regulations applicable to their own amount of experience

(d) The registry board shall be composed of licensed nurses of the State of New York and there shall be an Advisory Council to the Governing Board representing the medical profession and the laity

The above excerpts from a set of resolutions indicate that the nurses, themselves, are trying to remedy an evil we are all aware of and anxious to correct

We commend to the medical profession an attitude of co-operation in this movement instituted by the nurses

The twelve hour schedule presents the greatest difficulties and a problem which we frankly admit we are unable to solve. It is natural that a nurse should endeavor to adjust her life to that of her sister who gains her living in other fields, and is able to do so with less hours of labor and often under more agreeable surroundings. A fair regard for the health and physical endurance of the nurse should enter into the equation. Patients and some physicians have been most unreasonable in their demands upon the nurse in respect to hours of service, and doubtless these facts have contributed in no small measure to the present movement for shorter hours. We deplore, however, an arbitrary rule or demand for a limit of twelve hours duty. We feel that circumstances

and reasonable schedules to fit the individual case should determine in every instance

As regards disinclination to do certain types of nursing and assumption of the role of the physician, we believe these to be less frequent than asserted. They are, in any event, an expression of the personality of some individuals and beyond the power of anyone to control

After all, the nurse is quite as much concerned in these matters as the physician or the public. She is entitled to be heard, and should have opportunity to give expression to her ideals of training and of service after being trained

In regard to increasing the number of nurses for domiciliary service, much can be done both by the public and physicians to make this department of nursing more attractive than it is at present.

The committee believes a more general use of the "Trained Attendant" in ordinary and simple cases is desirable, and it is suggested that the small hospital which in the very nature of things cannot hope to conduct schools for registered nurses, might profitably conduct schools for "Attendants" and endeavor to dignify this type to the place it deserves in general scheme

We regard the Nurse Problem possibly the most important economic questions now confronting us. We therefore recommend

(a) That a Nurse Committee be appointed by the President to work in conjunction with the Committee on Economics to study the problems of the nurse and report annually or oftener to the Society

(b) That the same committee be authorized to confer with the State Education Department on matters concerning Nurse Education, and especially on that which concerns the proper balance of theoretical and practical training and instruction

Respectfully submitted,

ARTHUR W. BOOTH, *Chairman*,  
GEORGE W. KOSMAK,  
ALBERT T. LYTLE.

April 15, 1925

The Reference Committee recommended that a committee be formed to continue the study of the nursing problem (see page 814)

## REPORT OF THE COMMITTEE ON MEDICAL ECONOMICS

*To the House of Delegates*

At the closing of the meeting of the House of Delegates in 1924 this Committee was left with seven economic problems for its further consideration and report

They were

- 1 The Work of the New York State Council of Rural Workers
- 2 Nursing Problems
- 3 Health Insurance
- 4 Workman's Compensation
- 5 The Medical Practice Act
- 6 Health Centers with special reference to the plan adopted by the Medical Society of the State of California
- 7 Pay Clinics

During the current year the increased activities of the advocates of birth control have attracted notice and your committee has had the subject under consideration

A special committee was appointed by the House of Delegates to consider the nursing problem. As this committee has not communicated with the Committee on Economics, we assume that its functions were concerned with specific problems and that our reports will not conflict

1 The work of the New York State Committee of Rural Workers was participated in by your committee. The group forming the Committee of Rural Workers was acting under direction of the General Education Board and the specific problems were those associated with the distribution of physicians in New York State, a part of a general survey covering the United States. In its completed form the report was published by Drs Lewis Mayers and Leonard V Harrison, under the title "The Distribution of Physicians in the United States"

Aside from general discussion within your Committee, the entire work was done by one member, Dr Stanton. When it is understood that data such as these form the bases of the activities of social welfare workers you will realize that the methods of the collection of these and similar data as well as the very nature of the data is wholly subject to the discretion of the collector. Therefore that those unaccustomed to or for any reason unfamiliar with data bearing upon any specific problems and to their evaluation are open to mistakes which may provide useless and misleading statistics. The importance of the work done by Dr Stanton in advising in the above particulars is difficult to overestimate. Your committee urges that this Society go on rec-

ord as seeking to cooperate in any preliminary work of a social character which may be undertaken by any established and ethical group of social workers. In making this recommendation your committee recalls that when it requested the privilege of following the work herein reported, the House of Delegates, by specific action, restricted its activities

2 The Nursing Problem. Before submitting its report the chairman of your committee wishes to correct an error in the report of last year. The report contained the statement that an advance in prices was made at the direction of the State Society of Registered Nurses. This report was so made to the chairman by members of one of the component parts of the state organization, when, as a matter of fact, the action was taken only by the local Society and not recommended by the State Society of Registered Nurses.

The nurse problem is not unique in the field of supply of necessities of all kinds, it is merely the furnishing of adequate nursing care at a cost which can be met. The preparation of the nurse is, perhaps, somewhat more complicated than that of other commodities, but the same factors influence for or against. They are getting the raw material, shaping it for distribution and delivering it at the market.

According to the report of the Schools of Nursing, issued by the State Department of Education, the raw material is not lacking, the number of pupil nurses entering training in 1924 was 31 per cent more than in 1914, while the number of occupied hospital beds, which means teaching facilities, have increased only 29 per cent.

Primarily the problem is the preparation of our raw material for the market. There is no difference of opinion regarding the shortage of nurses. Accepting the above statistics there is only one answer to the problem, we must have more training facilities.

The simplest, cheapest and promptest remedy for this deficiency is shortening the course of study and thus enabling the training of a greater number of pupil nurses. Your committee is unable to quote the exact preponderance of the three-year course, but it is considerable. An immediate reduction of the course to two years in all training schools would increase facilities tremendously.

Further study of the figures given in the above mentioned reports shows that 14 plus per cent of girls who enter training in 1924 have dropped from the rolls for one reason or another. Fifty-six per cent of the number left training for reasons which, it would appear,

could have been foreseen, they either disliked the work, were not fitted for it, were incompetent, or guilty of misconduct. More care on the part of the admitting officers would therefore increase the effectiveness of our present facilities very considerably. The second method for increasing training facilities is, obviously, the building of more training schools. Just as obviously this will be a matter of slow growth, a feature of the general evolution of the hospital, not a problem of economists.

Unfortunately there are wide differences of opinion regarding the wisdom of such a move. But these differences are of scientific interest only and our need is too great for progress to wait upon scientific moot points. They can be just as interestingly discussed after the system is changed.

Many suggestions have come from as many sources, presenting methods by which nursing courses may be shortened. Last year your committee stated its opinion that the specific problems of nurse training are local. While our survey is far from complete it appears that more than 90 per cent of graduate nurses who continue practice remain in the districts in which they were trained.

This being the case the inference is that the training in the local schools, representing as it does the scope of the practice of the physicians working in the community, is sufficient to meet all requirements. Today the State Board of Regents requires pupil nurses in schools in small cities which do not include certain special nursing in their curricula, to spend certain months of their undergraduate lives in the schools of larger cities, pursuing the courses not given in their own schools. For the reason stated it is very improbable that the nurse will ever be called upon to utilize this special nursing. Such courses are practically economic losses, the nurses are absent from their own schools at periods in their training when they would be most useful, and are using room in larger schools which might be utilized to some practical end.

It does not appear from statistics that there is any general shortage of applicants for nurse-training. The subject of preliminary education is, therefore, not important at the present time. Even those who advocate reducing the educational requirements for admission to nurse training do not refute the fact that education is desirable if it can be had without interfering with the number of pupil nurses.

We find in occasional localities, however, that educational requirements do disbar some desirable material.

As a remedy for these conditions, remem-

bering our opinion that the problems are local, we advise that the system of entrance requirements be revised and examinations held, as is now done for Civil Service positions, in which other qualifications than education are given sufficient proportion of the total required minimum mark so that lack of high school education cannot in itself disbar the applicant from entrance to training schools. We present this as a recommendation to the House of Delegates.

In the matter of special nursing your Committee considers it an advanced subject and very probably and preferably post-graduate work. We believe that such classification leaves the choice of special subject to the nurse and thereby guarantees a much higher type of special nursing than it is possible to secure under present conditions. The economic loss at present entailed, as previously stated, is eliminated.

3 Health Insurance. Your Committee is of the opinion that Health Insurance, as such, is a dead issue in the United States. They are, however, many indications in the activities of various groups of social workers that Unemployment Insurance of some type is being sought. Care of the unemployed sick has been one phase of the subject which has had considerable attention and which will continue to be an important part of the whole subject. The stand taken against health insurance by the medical profession in New York State undoubtedly had a far reaching influence and did more to unify the profession than any other one thing in the history of medicine. It is not conceivable that any serious effort will again be made to subsidize medicine as the hand-maiden of the public. But it is essential, if we are to maintain the position which we have won by our unified fight, that we should show ourselves willing to become a deciding and guiding factor in any social efforts which we consider will be of benefit to the public of the State. We recommend, therefore, that if any definite effort is made toward the above ends this Society indicate its desire to be considered willing to participate in general discussions and to act in an advisory capacity where occasion offers.

4 Workmen's Compensation. Last year your committee expressed itself opposed to the proposed amendment to the Workmen's Compensation Law enabling free choice of physicians by the injured, giving the reason that, while the present system was open to irregularities, the employer and interested insurance carriers were in better position to select competent surgeons than the individual employee. This was not approved. The

amended bill presented at the last session of the Legislature, giving free choice of physicians, was ably supported by the Committee on Legislation. The bill was defeated.

Your Committee acknowledges the importance of the general principle involved. That is that the best interest of our form of Government is served by the fullest exercise of personal liberties, but in this instance a survey made of an up-state county decided your committee that the position which it took and continues to hold is productive of most good.

We find, in this instance, that the objects aimed at, i.e., the promptest return to work of the injured person, with a minimum of permanent damage from his accident, are probably being attained at present. The opinion is based upon the relative amount of surgical experience of all the practitioners in the district and that of those few who were selected by the employers to do the bulk of the work. Added to this your committee was able to estimate roughly the distribution of the general practice amongst the several physicians. From these inquiries, we find that, provided the majority of injured persons sought the services of their family physicians which we assume that they would do, they would fall into less expert hands than they do now under the present arrangement.

We repeat, therefore, our recommendations of last year that the amendment to the Workmen's Compensation Law permitting free choice of physicians is not desirable.

5 The Medical Practice Act. Members of your committee disagree concerning the advisability of the Medical Practice Act as embodied in the Karle-Dunmore bills presented at the last session of the Legislature.

Three opinions were presented. One in favor of the bill. One opposed to it on the ground that it taxed the medical profession for the benefit of the public and put upon it certain responsibilities of law enforcement which were unjust. Those in favor of the bill, including the chairman who acted as chairman of the committee which made the original draft of the bill a number of years ago in co-operation with the State Department of Education, favored it because it appears to be the only method of gaining the full support of the State Board of Regents and prompt prosecution of illegal practitioners. While taking this position for the reasons stated, the chairman feels that the blame for the present unfortunate conditions rests entirely with the Board of Regents. That body has been placed in supreme authority by law. It has accepted its obligation only in part. It has made certain definite regulations governing the granting of licenses to practice medicine. Perhaps wisely and

with the advice and approval of some of our medical colleges, but certainly very positively and at times even arrogantly, it has from time to time increased the requirements necessary to registration. It holds the power of revocation of license and exercises it. In brief, it holds the practitioner of medicine in the hollow of its hand and then it sits quietly down and refuses the physician who has complied with all its regulations at the expense of great labor and money, protection from the competition of illegal practitioners, of the followers of cults and of criminals of similar activities. Except that the majority of mankind is inherently decent there would be no legal practitioners of medicine for the Board of Regents to license. Certainly they offer no inducement to a man to follow a prescribed course of study and live up to regulations while the individual who has no sense of decency or of responsibility to his fellow men can enjoy greater financial gains in doing the same which the licensed physician is doing and without the slightest interference—unless he happens to kill a patient or otherwise attract the attention of the police.

The law places the prosecution of illegal practitioners with the district attorneys of the several counties. It does not, however, compel him to go out and get evidence until a case is presented to him. The moral responsibility for procuring and presenting evidence rests upon the Board of Regents. It is its duty to and is within its power to rid the state of those who continue to menace the public health by their illegal activities. The practical attitude of the representatives of the Board of Regents has been that until the medical practice act could be so amended that the medical profession could furnish the first information of illegal practitioners, the Board would take no action. It is only after years of personal effort to secure the passage of better medical legislation and an act similar to the Karle-Dunmore bill of last session that the chairman of your committee has reached the conclusion that such legislation is next to impossible, and that attempted co-operation of the Medical Society of the State of New York with the State Board of Regents to attain such ends is futile. He takes this opportunity, therefore, to present his views for which he assumes sole responsibility. Whether the balance of the Committee would subscribe to the foregoing or not has not been ascertained.

Opposition to the Karle-Dunmore bill from another member of the Committee is offered on the basis of previous experience in failure to enforce medical practice acts and the results of such failure. Such efforts have usually meant that the prosecuted practitioner easily assumed the role of martyr and the reaction has done more harm than good to the medical profession. He offers as a remedy for the existing evil the

passage of a law making possible civil suit for mal-practice where injury is done an individual by an illegal practitioner. He cites the recent case in Utica of *Brown vs. Shane*, a chiropractor, in which a verdict of \$10,000 was obtained against Shane for mal-practice. In this case Judge Edcomb ruled that practicing medicine without a license is in itself evidence of negligence, and that acceptance of treatment by an illegal practitioner is not in itself contributory negligence. Whether this will stand an appeal is, of course, uncertain, but whether it is good law or not, it is good sense that where the State permits such practitioners to openly advertise and pretend to cure disease it can not be expected that the average citizen can be aware of the danger which he runs in consulting such a person. The English law has long placed the illegal practitioner in a position where he is practically unable to defend himself against mal-practice suits and the general results have been satisfactory. Dr. Stanton, of your Committee, proposes the following amendment to the Medical Practice Act

"No provision of the act shall be construed as in any way preventing an individual who may have been injured as a result of unskilled advice or treatment entering suit for civil damages against a person practicing medicine who has not complied with the requirements for licenses as defined in this act. In case such a suit is instituted against one practicing medicine without a license the fact that the defendant has not complied with the educational and other requirements for licenses shall be interpreted as presumptuous evidence of negligence on the part of the defendant."

The above is subject to legal phrasing

The adoption of such an amendment as that practically removes any defense which the defendant may assume to have

The menace in malpractice suits is appreciated by B. J. Palmer, Secretary of the Universal Chiropractors' Association, in an open letter to members of that cult in which he urges them to join the Association, and thus avail themselves of the services of attorneys especially qualified to defend such activities. It is the opinion of your committee that this foregoing is worthy of serious consideration.

**6 Health Centers** The situation so far as state control of health centers is concerned has remained unchanged.

It will be recalled that three years ago your committee reported on the resolution passed by the Medical Society of the State of California requesting cooperation of the members in a plan which practically made every physician's office a "health center." By this plan each member was to undertake to see that any one calling upon him, regardless of the appli-

cant's financial status, should be put in the way of securing adequate medical care. In this manner it was expected that it could be demonstrated that no person or group of persons or any organizations or State department need be interposed between the physician and the patient. The plan reduced the adequate care of the sick to the simplest possible form, and, should it prove successful, would be one great step toward complete control of all medical activities by physicians in active practice, a most desirable thing from a humanitarian as well as an economic viewpoint. Your committee last year reported progress in California. That is all it can do this year because the secretary of California Medical Society has not made a final report. As we view this method we consider that one of the practical obstacles in its progress is difficulty of advertising. It is going to take the people who would benefit most a long time to know what they can expect.

Today we are awaiting the development of a great medical center. If the prestige of associations with educational institutions and educators of first rank can guarantee success, the Columbia College-Presbyterian Hospital Center must succeed.

Unlike other medical centers this presents no economic problems for the medical profession. Its educational position is beyond question and it should be regarded as the real beginning of America's rise to its logical position as the medical center of the world. It would be a remarkable achievement if some association of the State Society with the center could be brought about. If it could be no closer than the mere meeting of our scientific sections at the Center the influence upon medical practice in the State would effect more rapid advances than could be expected from almost any other plan with which we are familiar.

**Pay Clinics** Under this heading we have previously considered the Cornell Medical College Clinic. While every attempt has been made to avoid competition with physicians in private practice, there are some points at which such competition occurs. Complaints from physicians have become less frequent, however. We are unable to judge whether this is because the newness is wearing off or because the institution has become generally accepted as another economic evil which has to be endured. Your committee has no recommendation to offer. It is our opinion that, at present, we cannot offer our official endorsement of the movement. The report for the current year has not been received.

**Birth Control** During the current year the advocates of birth control have increased their

activities The strength behind their legislative efforts was not inconsiderable, though at no time was there any serious possibility of their bill being enacted The arguments for birth control are too well known and of too little real consequence to require discussion in this report Your committee recommends, however, that the House of Delegates record itself in opposition to the measure

**Occupational Instruction** The Federal Government is enlarging its staff of instructors for manual training amongst—or those who are, for one reason or another, entitled to such training This field offers an opportunity for both men and women who wish to enter a field which is practically a branch of nursing The medical profession can be of assistance to the Government by advising eligible persons of the existence of this work Training in this field will prepare for private vocational work, especially among the insane, where the value of this form of therapy is constantly receiving more recognition

**Fee-Splitting** A communication on this subject was received by your Committee from the Bronx County Medical Society, but after investigation your Committee considered that this matter had better be presented by the delegates from Bronx County and have advised that body to that effect

We reached this conclusion because we are unable to agree as to proper recommendation to the House of Delegates The college of surgeons has, of course, the privilege of making whatever rules it may for its own members, but it is our judgment that the Bronx County Society is following the proper course in asking the House of Delegates to pass upon a question of ethics As a matter of custom the American Medical Association, and its constituent state societies, has the authority to establish a code of ethics, and it is very

questionable if any special society is not arrogating to itself privileges to which it has no legitimate claim when it attempts to promulgate an ethical code It may make rules for its own members only It is the opinion of the majority of your committee that matters of ethics interesting special societies should be introduced only through the House of Delegates of the American Medical Association, where, if favorably passed upon, they will become parts of the code of ethics of that body, to which all state societies subscribe

In the opinion of your committee a grave question of ethics is involved in the publications, in lay journals of the articles referred to in the communication from the Bronx County Society If the articles were either prepared or sponsored by the American College of Surgeons it is the majority opinion of your committee that the college is not above reproof We are, however, unable to decide upon this point Some members of your committee are sure that the College was unaware of the publication, and others, claiming to speak with definite knowledge, state that the articles were inspired by that body

Because of these differences your committee is only prepared to recommend that this matter be given the serious consideration of the House of Delegates

The foregoing is respectfully submitted,

Henry Lyle Winter, *Chairman*  
J. Richard Kevin,  
George W. Kosmak  
William H. Purdy  
Edwin MacD. Stanton

The Chairman of the Committee on Medical Economics has an individual report to submit As this contains no recommendation for action of the House of Delegates, he begs the privilege of presenting same through column of the Journal

Report referred to Council

## REPORT OF COMMITTEE ON POST-GRADUATE MEDICAL INSTRUCTION

### *To the House of Delegates*

The Committee on Post-Graduate Medical Instruction reports that they have considered carefully much data on Post-Graduate Medical Instruction in the different states and have had informal talks with officials in the State Education Department and State Department of Health who are decidedly in sympathy with this movement and who would be helpful if some method of graduate instruction should be put into action

In 1912-1913 Germany inaugurated a system of Post-Graduate study University Professors visited remote country districts and delivered clinical lectures to physicians who could not afford to study away from home This scheme was to have been a prominent feature at the International Medical Congress which terminated dramatically in London in August, 1914

### WISCONSIN

The University of Wisconsin began actual graduate medical teaching in September, 1917, in ten of the largest cities of the state This work has continued most successfully and has been increased in its scope from year to year "Interest has grown and there is no question as to how the physicians throughout the state feel about the work"

### PENNSYLVANIA

The University of Pennsylvania with the Medical Society of the State has initiated a plan of University Extension Post-Graduate Instruction

Under the plan a sharp distinction is drawn between the character of the teaching in Philadelphia (and perhaps later, Pittsburgh) and that conducted in other extension centers "Physicians throughout Pennsylvania have shown the keenest interest in our plan of University Extension Post-Graduate Instruction" The need and the desire both exist and the difficulties met all center around the question of expending enough money to produce true efficiency

### NORTH CAROLINA

In 1916 Post-Graduate courses in pediatrics were given in twelve communities of North Carolina under the auspices of the State Board of Health and the Medical Department and Extension Division of the University of North Carolina Two instructors from Boston and Chicago respectively were appointed and each assigned to six centers which were covered daily in rotation every week for four months

The war interrupted further work and it was not until 1921 that it was again taken up

Internal medicine was now chosen and two

instructors from outside the State (Boston and Chicago) were assigned to two circuits of six centers in 1922 for 12 exercises

"The work has shown a steady growth in both interest and attendance Doctors have had to drive on the average twenty miles each way in order to attend lectures and clinics" "Our work has passed the experimental state and we know that there is a real field for this kind of program We expect to put on two circuits covering twelve centers every Summer"

### BROOKLYN EXTENSION PLAN

Joint Graduate Education by the Medical Society of the County of Kings and the Long Island College Hospital

(1) Practical lectures at 5 p m for one hour on Fridays during a spring and a fall term

"Each talk was simple, practical, clinical and fundamentally sound There was no discussion but questions were encouraged The program met instant and lasting success At every meeting the auditorium was filled to overflowing and at some lectures a great many turned away"

(2) Graduate Courses Seven intensive and twenty-seven extensive courses "Our experience indicates that this type of work is appreciated by the profession" "Our next problem is its extension into the dispensary and also some consideration of the re-arrangement of hours for the greater convenience of the busy practitioner" "We are also sensing a demand for more advanced work of an intensive character which it is our hope to meet"

Your committee feels that as education in medicine is never finished and as a large majority of the profession desires to keep pace with the science of medicine which in the last twenty years has undergone a development probably not equalled or even approached by any other science that some determined effort must be made to render the practical results of this scientific progress available to practicing physician—the man behind the gun

The value of the discoveries by splendidly endowed research laboratories and well equipped hospitals for the direct benefit of mankind is inestimable and yet how little of this knowledge seeps through to the practicing physician and how much is therefore out of the research of the public In spite of millions spent in research no effort has been made to carry the great truths discovered in medicine to the cross-roads physician (both in the country and city) who is every day striving with all his might to fight off death and to relieve suffering

Continuous and effective education of the

practicing physicians must be recognized as the greatest possible contribution that can be made to the public health. This committee therefore believes and recommends that the Medical Society of the State of New York should take immediate steps to organize an efficient and practical system of graduate medical instruction which will place within reach of every physician for the service of his patients and the state all the usable results of the tremendous progress constantly being made by medical science.

This committee also urges and recommends that a special committee be appointed with power to put into immediate effect a plan of

graduate medical extension instruction which will meet the greatest need today in the medical profession and which will place this, the Empire State, in the van of constructive and efficient medical service.

Respectfully submitted,

ANDREW MACFARLANE,  
*Chairman*

GRANT C. MADILL,  
JOSEPH C. PALMER,  
CHARLES STOVER,  
GROVER W. WENDE

The recommendations were approved (see page 807)

## REPORT OF COUNSEL FOR THE PERIOD FROM MARCH 1, 1924, TO APRIL 1, 1925

### To the House of Delegates

Counsel herewith submits his report for the period of thirteen months since the last annual meeting of the House of Delegates covering the various phases of his activities.

TABLE I

	Suits Instituted	Suits Dis- posed of
Mar 1922 to Apr 1923	121	40
Apr 1923 to Mar 1924	108	56
Mar 1924 to Apr 1925	181	129
<b>Totals</b>	<b>410</b>	<b>225</b>
Excess of suits instituted over suits dis- posed of from Mar 1922 to Apr 1925		185
Pending Mar 1922		99
Pending Apr 1925		284

An examination of this table indicates that since March, 1922, despite the fact that we have disposed of 225 suits, that there has been an excess of suits received over those disposed of, of 185. This means that there is a constantly increasing congestion of these cases in our office and that until the number of cases received drops to a level with our present capacity to dispose of the business, that our calendars will remain clogged. To dispose of the present pending calendar, were no new cases to be received, it would take approximately two years with two active trial lawyers participating in the trial of the cases. It is our plan to add a third trial man in our office to assist in cutting down this pending calendar.

TABLE II  
COMPARISON OF NUMBER OF SUITS INSTITUTED AND  
DISPOSED OF

	Instituted 1923- 1924	1924- 1925	Disposed of 1923 1924	1924- 1925
1 Fractures, etc.	17	14	1	25
2 Obstetrics, etc.	11	26	7	20
3 Amputations	1	0	0	1
4 Burns, X-ray, etc.	11	16	3	9
5 Operations—abdominal, eye, tonsil, ear, etc.	25	36	14	21
6 Needles breaking	0	4	1	2
7 Infections	2	9	6	7
8 Eye infections	1	2	1	3
9 Diagnosis	7	10	4	8
10 Lunacy commitments	0	2	6	3
11 Unclassified—medical	13	20	5	8
12 Loss of services, wife, child	20	42	8	22
<b>Totals</b>	<b>108</b>	<b>181</b>	<b>56</b>	<b>129</b>
<i>Further comparisons</i>				
Action for death	7	15	5	10
Infant actions	8	17	5	15
	<b>15</b>	<b>32</b>	<b>10</b>	<b>25</b>
<i>How disposed of</i>				
Settled				7
Dismissed, discontinued or tried (verdict for defend- ant)				92
Judgment for plaintiff				00
Dormant cases—marked off ac- tive list				30
<b>Totals</b>		<b>181</b>		<b>129</b>
Pending on March 31, 1925		<b>284</b>		

An analysis of the cases instituted and disposed of according to the different types is usually of interest to the physicians. It will be noted from examining Table II that the number of death actions last year was about twice that of the previous year and the actions by infants also twice that of the previous year, and similarly with actions based upon obstetrical and gynecological procedures, ac-

tions based upon operations increased 40 per cent, those arising by reason of infections were four times as many as the previous year, actions based upon diagnosis increased 40 per cent, the division of actions between general practitioners and specialists is about half and half, there being 92 actions against specialists and 89 actions against general practitioners, whereas in the disposition of cases we disposed of 55 actions against specialists and 74 against general practitioners, whereas fractures have always been a fruitful source of malpractice actions, the past year has shown a decrease over the previous period in actual numbers of cases received. This fact is quite significant when one considers that the normal increase in cases received during 1924-1925 over the previous year was about 70 per cent and at that rate the normal number of fracture cases to keep pace with such general increase in the number of cases would have been twice the number that actually were instituted. This shows a healthier condition from a malpractice standpoint in the fracture field. The increase in the obstetrics is a little more than normal in comparison with the general increase. The increase in suits based on infection is quite out of proportion with the general increase.

In the disposition of cases, it will be noted that no case was lost, although 7 were settled and 92 were disposed of by dismissals or successful trial. The cases that are marked dormant, numbering 30, that are marked off the active list, are a number of old actions which have not been moved for trial by the plaintiffs and probably never will be. These were marked off as a merchant would mark off bad debts, so as not to carry them over each year.

TABLE III  
APPEALS

	1923 1924	1924 1925
Appeals taken	9	3
Affirmed for plaintiff	0	0
Affirmed for defendant	0	0
Plaintiffs judgment reversed	0	2
Defendants judgment reversed	0	4
Withdrawn	0	2

It will be noted in Table III that three appeals were taken during this period, and that cases which were lost in the lower court were won on appeal in two instances, and cases won in the lower court were reversed on appeal and new trials ordered in four instances, and two appeals were disposed of by plaintiff withdrawing the appeal, so that there was a total of eight appeals disposed of during the last year.

By reason of the showing that we have been able to make in the past year, despite the substantial amounts that have had to be paid in the settlement of the seven cases mentioned, it will not be necessary to raise the rates for the

group insurance during the coming year. This group insurance plan is being carried out in accordance with the understanding originally had, to the end that there may be made available to the members of this Society malpractice indemnity of the highest type based upon actual cost computation and backed by a responsible company.

TABLE IV

During this period, your counsel has prepared for publication in the Society's Journal, articles in the nature of editorial comment of interest and benefit to the members. The editorials include the following

"Physicians' and Surgeons' Liability Insurance",  
 "Liability When a Physician Leaves a Case in Charge of Another Physician",  
 "Chiropractor Held Liable for Malpractice",  
 "Chiropractor Convicted of Manslaughter",  
 "Interpretation of the Law in Malpractice Cases",  
 "Medical Societies and Their Relation to the Problem of Medical Licensure",  
 "Recovery of Compensation by Physician",  
 "Drop a Nicoll Bill in the Legislative Slot and Receive a Doctor's Degree",  
 "The Nicoll Chiropractic Bill",  
 "Medical Testimony and Comment upon Judge's Charge in a Malpractice Action",  
 "Registration and Other Features of the Karl-Dunmore Bills",  
 "March Fourth at Albany",  
 "Conviction under Harrison Narcotic Law and Its Effect on a Physician's License",  
 "Five Thousand Physicians Should Think This Over",  
 "The Mission of Organized Medicine Today",

Some of the Cases which have been disposed of by Counsel in the past, have been digested and published in the Journal, among which were the following

"Swallowing Foreign Body — Resultant Bronchial Pneumonia and Death",  
 "Claimed Improper Prescribing of Tanningen for Child Suffering from Diarrhoea",  
 "Colles' Fracture",  
 "Breaking Needle in Lumbar Puncture",  
 "Needle Breaking in Pleurisy Aspiration Complicated with Empyema and Pregnancy",  
 "Alleged Abandonment During Confinement",  
 "Treatment by Immobilization of Tubercular Ankle Results in Suit",  
 "Amputation of Finger—Defense of Workmen's Compensation",

"Appendicitis—Alleged Delayed Diagnosis",  
 "Gauze Claimed to Have Been Left in Abdominal Cavity on Performance of Appendix Operation with Resultant Ventral Hernia",  
 "Multiple Extraction of Teeth under General Anesthesia—Gold Crown in Lung with Resultant Death",  
 "Claimed Prong and Cotton Left in Abdominal Cavity upon Appendectomy",  
 "Claimed Conspiracy in Insanity Commitment",  
 "Broken Needle in Abdominal Operation",  
 "Termination of Pregnancy Due to Kidney Trouble Caused by Alleged Improper Treatment of Obstetrician",  
 "Alleged Negligent Attendance of Mother and Child at Childbirth",  
 "Removal of Nasal Hump and Resection of Deviated Septum",  
 "Removal of Uvula in Performance of Tonsillectomy and Adenectomy with Claimed Resultant Impairment of Speech",  
 "Alleged Failure to Have X-Ray Taken and Diagnose Fracture",  
 "Retained Placenta—Puerperal Septicemia—Death"—  
 "Pregnancy—Complicated by Cystitis—Dry Labor—Metastatic Abscesses",  
 "Claimed Wrong Diagnosis of Pregnancy",  
 "Mental Examination Insanity Commitment",  
 "Claimed Nasal Operation on Minor Without Consent of Parent",  
 "Claimed Wrong Diagnosis and Improper Advice",  
 "Operation Without Consent",  
 "Salpingitis Claimed Due From Stem Pessary Inserted by Physician",  
 "Non-Pregnancy Leucorrhoeal Discharge, Attempt to Curette, Subsequent Ovariectomy",  
 "Fractures of Both Femurs Delayed Union, Gangrene of Left Foot and Leg with Amputation",  
 "Prolapsed Uterus"

In addition to the correspondence necessary in the handling of the malpractice cases, general correspondence during the period has included the following

Request for advice regarding ownership of X-ray films—Answer thereto  
 Communication from the President enclosing letter sent to House of Delegates  
 Communications from the office of the Society enclosing report  
 Communication regarding law on X-rays  
 Communication from the Society regarding case to be written up for JOURNAL  
 Communication from the Society regarding action of the Department of Education upon doctors convicted under Harrison Narcotic Law  
 Communication regarding contract of employment of the Executive Office.—Preparation of said contract.  
 Response regarding legal status of men convicted under Harrison Narcotic Law  
 Communication regarding certain insurance claim and answer thereto advising doctor respecting same.  
 Communication regarding article on medical licensure.  
 Communication regarding meeting for the defining of duties of new Executive Officer—Attendance at said meeting thereafter  
 Communication from Kings County Medical Society regarding malpractice insurance.  
 Communication from the Secretary of the Federation of Medical Boards  
 Communication regarding letter of Post Office Inspector  
 Communication regarding issuance binders of insurance to applicants for membership  
 Communication regarding the practice of group medicine in a certain city, requesting advice thereon—Answered

Communication from Connecticut Chamber of Commerce enclosing questionnaire—Answered.  
Communication from the Board of Censors of a County Society regarding action upon a physician.  
Communication regarding chiropractic.  
Communication regarding invitation to address Society of Medical Jurisprudence  
Communication from a Society in regard to automobile insurance—Answer thereto  
Request for information from the American Medical Association—Answer thereto  
Communication from Counsel of the New York County Medical Society and answer thereto  
Communication from the District Attorney of Kings County conveying information regarding an unlawful practitioner in that County  
Communication from the Secretary of the New York Medical Society involving question of medical ethics  
Communication to the Department of Education at Albany regarding status of a claimed medical practitioner—Answer thereto  
Communication from the Secretary of the Medical Society of New York County regarding qualifications of membership  
Communication with the Medical Society of the County of New York regarding amendments to by-laws, with advice thereon  
Communication with attorney for podiatrists regarding use of title Dr  
Communication from Counsel of the New York County Medical Society and answer to inquiry contained therein.  
Communication regarding liability of roentgenologists and answer thereto  
Invitation to address Eastern Section American Roentgen Ray Society  
Receipt of report of committee regarding the nurse question in the County of Erie.  
Communication from the President of the Society regarding bill pending in legislature—Preparation of letter advising regarding said matter  
Invitation to speak before the Sixth District Branch and answer thereto—Further communications respecting same matter  
Invitation to speak before a local medical society and response thereto  
Communication from County of Albany regarding change of by-laws and answer thereto  
Communication from the Department of Health of New York City regarding certain nostrum and answer thereto  
Request for articles by the Counsel on inheritance and transfer tax subject.

Advice asked concerning possession by doctor of an X-ray plate and answer thereto  
Request for advice on the law respecting operation on minor and answer thereto  
Communication from the State Medical Society regarding communication from the County Society of Schenectady  
Advice to the State Medical Society regarding request of Bronx County Medical Society for ruling on status of dentists as possible associate members of the Medical Society  
Request for advice on possible claim against a physician for the use of X-ray—Advised thereon  
Communication from Dr Hubbard regarding the use of title Dr

Communication regarding medical defense in another State answered with information concerning our experience in New York.  
Communication from physician asking for advice regarding ethical question—Answered.  
Communication seeking advice regarding status and rights of physician on hospital staff—Advice given  
Communication regarding local ordinances restricting doctors and advice thereon.  
Communication regarding unlawful practice in Kings County and reference of matter to the District Attorney of that County  
Communication regarding claim of patient against a physician for malpractice.  
Communication regarding legality of a corporation engaging in X-ray work and answer thereto  
Communication requesting advice regarding methods of prosecution of illegal practitioners and answer thereto  
Request for advice from up-State lawyer regarding claim of malpractice against a physician.  
Three-page opinion with respect to methods of prosecution of illegal practitioners  
Request for a medico-legal opinion.  
Request for legal opinion by physician—Same given—Further communication regarding same.  
Request from up-State physician for advice regarding alleged unethical practice of another physician  
Request for information from Secretary of Board of Medical Examiners of the State of California—Same answered—Further communication with respect to the same matter—Investigation of files of New York County Medical Society and information requested communicated.  
Invitation to speak before the First District Branch—Answer thereto  
Invitation to speak before the Harlem Medical Association and answer thereto  
Request for information as to legal status of officer of a county medical society against whom charges had previously been preferred—Same answered.  
Request from firm of attorneys in Alabama respecting article on liability of physicians written by counsel—Same answered and citation of cases given  
Communication from Post Office Inspector regarding advertising of certain physician and answer thereto  
Communication from a physician heretofore convicted under Harrison Narcotic Law regarding his legal status and answer thereto  
Communication regarding procedure for prosecution of unlicensed practitioners and answer thereto  
Invitation to address a County Medical Society  
Communication with the Legislative Committee.  
Communication from President of the Medical Society regarding inquiry as to the status of osteopaths in city hospitals.  
Legal opinion regarding certain publication in the Medical Journal.  
Communication with American Medical Association regarding model practice act  
Invitation to speak to an up-State County Medical Society on legislative matters  
Request for information regarding right of an alien practitioner to practice here—Answer thereto

The questions referred to in these communications often require considerable investigation and careful thought and frequently involve the giving of legal opinions and careful analysis and interpretation of legal questions

## ATTENDANCE UPON MEETINGS, ETC

Counsel has personally attended or been represented at each of the meetings of the Council and Executive Committee during the year. Some of the matters considered are the following:

At the request of the Medical Society of the County of Queens, interpretation of Section 31, Principles of Professional Conduct Concerning Advertising, particularly relating to signs of doctors which advertise a specialty, such as eye, ear, nose and throat.

Consideration of the correspondence between the University of the State of New York, the Board of Medical Examiners, Assistant Commissioner of Higher Education, Secretary of the Board of Medical Examiners, and the Medical Society of the County of Schenectady upon the question of excluding certain names from the Directory of the Society. Opinions and letters were written upon this subject.

Consideration of proposed amendments to the by-laws of the Medical Society of the County of New York, which was referred to counsel, and advice thereon.

Attended meetings of the Medical Society of the County of New York, Medical Alliance, Society of Medical Jurisprudence—discussed Karle-Dunmore Medical Practice Bill, explaining the position taken by the Medical Society of the State of New York thereon.

Attended a meeting of the Eastern Section of the American Roentgen Ray Society at Atlantic City and read a paper upon "The Legal Hazard of the Roentgenologist in the Practice of X-ray Therapy."

Attended meeting of the First District Branch, was represented at meetings of the Sixth and Eighth District Branches by Mr. Robert Oliver, where my paper was presented entitled "Medical Societies and their Relation to the Problem of Medical Licensure." Mr. Oliver read a paper on "The General Law of Malpractice" at the Harlem Medical Society and the same paper at the meeting of the Society for Clinical Study.

## LEGISLATIVE MATTERS

Counsel, in consultation with the Department of Education and the Department of Health of the State and under the advice and direction of the Executive Committee of the Society, prepared what later became the Karle-Dunmore Medical Practice Bill for the Legislature of 1925. This bill was based in considerable part upon the bill previously introduced known as the Carroll Bill, drafted the substance of a bill eliminating the statutory necessity of electing censors each year, and leaving the manner of their selection to appropriate provision by by-laws of the Society, analyzed

and reported upon the various "cult" bills, including the Nicoll, Esmond, Fearon and Boulton chiropractic or drugless therapy bills, prepared memoranda thereon for the Joint Committee of the Assembly and Senate on Public Health, appeared before the said Committee in the Assembly Chamber and spoke in behalf of the Karle-Dunmore Bill and against the various "cult" bills, and prepared the form of question for referendum vote of the House of Delegates on the Karle-Dunmore Bill, and was a member of the Committee of tellers to consider and count the votes.

Counsel consulted with representatives of certain local medical societies with respect to the Karle-Dunmore Bill, and after a long conference gave written answers to numerous questions submitted, analyzed and reported to the Committee on Legislation upon a bill requiring physicians to furnish certain clinical data when using supplies distributed by the Department of Health. Gave opinion to the Committee on Legislation concerning amendment to Section 188 of the Workmen's Compensation Law, and gave opinion to the Committee on Legislation respecting bill giving right to an injured workman to select his own physician.

During the past year a considerable number of physicians have unselfishly devoted their time in aiding counsel in the preparation of cases by giving advice on medical and surgical procedures and have appeared as expert witnesses at the trials. This service has in each instance been greatly appreciated by the doctor-defendant and has been equally gratifying to counsel. The spirit displayed by these men of pre-eminent ability and outstanding reputation in their various specialties has been a great inspiration to counsel in the work of defense. It is the desire of counsel to express, in this report, his thorough appreciation of their sacrifice and effort in bringing before the courts expert testimony of rare value, based upon truly scientific facts. Were the expert testimony of all branches of law to reach the high level of that which is offered in malpractice cases in behalf of the doctors who have been sued, there would be no stigma attached at any time to that type of testimony, but it would receive the great weight which it justly deserves.

Counsel also desires to express to the Council, Executive Committee and officers of the Society his thanks for their hearty and thorough co-operation in the performance of his task during the past year and to acknowledge the valuable aid given in the performance of all the duties of his office by Mr. Robert Oliver, his associate, as well as by the other associates of counsel in his office. Counsel has also received the active and hearty co-

operation of Mr Harry F Wanvig, who has charge of the administrative details of the group insurance plan in behalf of the Society and of the officers of the Aetna Life Insurance Company, who have co-operated in the handling and disposition of the cases arising under the group insurance plan, to whom he is grateful

The resolutions under which malpractice defense was originally authorized and has continued, particularly to members who have not availed themselves of the group insurance plan, require modification and change Under the group insurance plan, inasmuch as the expense of defense through to the highest court, if necessary, is met by the funds made available by the payment of premiums to the insurance company, the doctors insured under that plan receive the maximum of protection This protection is open to every member of the Society and those, therefore, who desire a type of defense that will carry them through the upper courts, which includes a large outlay for stenographic minutes, printing of records and preparation and printing of briefs, should be sure to procure that protection The Medical Society could hardly afford, under its defense plan for uninsured members, to carry on so expensive a practice In fact, it seems in the past this expense has generally been met in the upper courts by the particular doctor affected.

It is recommended at this time, however, that the resolutions be amended so as clearly to define the rights and privileges of members who do not avail themselves of the insurance plan That recommendation will include the right of such a member to defense through one trial, and the obligation on the part of the members to defray all future expense of the litigation should there be further trials or appeals to the higher courts

It is also recommended that the Executive Committee be given certain discretion in committing the Society to the defense of cases, as instances have arisen where the nature of the case was such as, in the opinion of the counsel, to make it inexpedient and inadvisable for the Society to be committed to the case Accordingly, the adoption of the following resolutions is recommended

"Members shall be entitled to malpractice defense of any suit arising from any one claim in each calendar year of alleged malpractice, error or mistake done in the performance of his profession as a physician

The Society shall not at its own expense ap-

peal from any judgment that may be entered against a member in any malpractice suit

The Executive Committee shall make a rigid examination of all the facts in any alleged malpractice claim or suit and shall also examine into the applicant's membership and standing in the Society and the worthiness of the applicant's case

The Society will not undertake the defense of any member who, after investigation by the Executive Committee, is believed guilty of criminal abortion, feticide, homicide or any criminal act or who has not complied with the recognized ethical laws in regard to these cases The Society will defend only suits brought for any alleged malpractice, error or mistake done or claimed to have been done in the legitimate performance of the duties of his profession as a physician

The Society shall not be obligated to defend any malpractice claim or suit against any member when such claim or suit is covered by any policy of insurance carried by such member But nothing herein contained shall be deemed to curtail, abrogate or restrict the rights of any member under the group insurance plan endorsed by the Society"

It is further recommended that the President of each County Society, during the coming year, preferably by November 1, 1925, shall communicate with the counsel of the State Society, after conference with an appropriate committee of such County Society, as to what, in the opinion of such officer or committee, is the underlying cause of the bringing of malpractice suits against physicians in their particular localities and what steps, if any, can be taken to discourage the bringing of groundless suits of this character, and furthermore, what steps, if any, can be taken to discourage publicity of such suits before actual judgment has been entered It appears that a great injustice is done, to a physician who is sued, by publication of the fact of such suit being brought against him, even though the suit be without merit It appears likewise that some patients bring suits for the purpose of discrediting the physician by such publication rather than by intending in good faith to press the suit to trial

Respectfully submitted,

GEORGE W WHITESIDE,  
*Counsel*

Dated April 1, 1925

The report and its recommendations were heartily approved (see page 809)

## REPORT OF THE COUNCILLOR OF THE THIRD DISTRICT BRANCH

### *To the House of Delegates*

The County Societies of the Third District Branch have not only held their regular meetings but many special ones have added to the scientific advancement of the members

The annual meeting was held at the Loomis Sanatorium, Loomis, Thursday, October 9, 1924 The following program was presented

Address of Welcome to the Loomis Sanatorium.

Bertram H Waters, M D, Physician in Chief

Address of Welcome from the Medical Society of Sullivan County

J Burns Amberson, Jr, M D, President

Artificial Pneumothorax and Surgery in the Treatment of Pulmonary Tuberculosis

Andrew Peters, M D, Loomis

Laboratory Aids in Diagnosis of Tuberculosis

J Stanley Woolley, M D, Loomis

The Differential Diagnosis of Tuberculosis Cavities in the Lungs

J Burns Amberson, Jr, M D, Loomis

Presentation of Cases

Luncheon at 1 30 P M

The State Society

Owen E. Jones, M.D., President Medical Society, State of New York, Rochester

Address

Arthur J Bedell, M D, President Third District Branch, Albany

The following officers were elected President, Dr Charles P McCabe, Greenville, First Vice-President, Dr Edgar Vander Veer, Albany, Second Vice-President, Dr Herbert L Odell, Sharon Springs, Treasurer, Dr Ernest E Billings, Kingston Dr Clark G Rossman, of Hudson, was re-elected Secretary

Respectfully submitted,

ARTHUR J BEDELL,  
*President*

April 15, 1925

## REPORT OF THE COUNCILLOR OF THE FIFTH DISTRICT BRANCH

### *To the House of Delegates*

The Annual Meeting of Fifth District Branch was held at Oneida, Thursday, October 2, 1924 The meeting was held at the recreation rooms of the Presbyterian Church Over one hundred doctors were present during the day Thirty or forty members' wives were present and were entertained by the wives of the local doctors

The ladies were given lunch and automobile drives, taken to the Oneida Community Silverware plant, and by the courtesy of the management were taken through the plant and on leaving were each given a souvenir spoon

A lunch and musical entertainment by the Madison County Medical Society was given the members

The Mayor of the City of Oneida, Arthur J Abbott, welcomed the doctors to the city and commended the profession for the splendid work which was being accomplished by the profession Dr Otto Pfaff, of Oneida, welcomed the men in behalf of the County Society

The President of the Branch recommended

that the members advocate periodic health examinations and also do work in their locality superior to what had been done in the past.

The program was a most interesting one. Dr George W Miles, of Oneida, gave an excellent paper on "The Function of Eating" Discussion opened by Dr Stephen L Taylor, of Sherrill

Dr Edward Livingston Hunt, Secretary Medical Society State of New York, presented a paper on "Poliomyelitis" Dr Charles D Post, of Syracuse, spoke on "Coronary Closure"

Dr Matthias Nicoll, State Health Commissioner, gave a talk on "Public Health"

Dr T Wood Clark, of Utica, spoke on "The Value of Gastro Intestinal X-Ray in the Diseases of Children"

Dr Thornhill also spoke All the papers and discussions were well received

Respectfully submitted,

NELSON O BROOKS,  
*President*

April 15, 1925

## REPORT OF THE COUNCILLOR OF THE SIXTH DISTRICT BRANCH

### *To the House of Delegates*

The last annual meeting of the Sixth District Branch of the State Medical Society was held on October 7, 1924, at Oneonta. Owing to the inclement weather and the geographical location of the meeting place, it was not as largely attended as usual, but what the assemblage lacked in numbers it made up in enthusiasm. A slight departure was made from the usual routine of scientific papers, and the matter of medical legislation was taken up at some length. Dr. Julian Smith of Oneonta, a member of the last Assembly, gave a most interesting and enlightening discourse on the Legislator's viewpoint regarding medical bills, which brought out some very healthy discussion. Thanks to the efforts of Dr. Wilbur Fish of Ithaca, we had the opportunity of seeing some very remarkable moving pictures of the work being done at the Cornell Medical School on the thyroid gland. The meeting this year will be held at Ithaca and doubtless it will be our privilege to see the continuation of this work.

The county societies comprising this Branch

have made a few changes in the number of their meetings. Broome County has changed its by-laws so that a regular meeting will be held every month now instead of four times a year as formerly. The subject of medical legislation has had a very prominent part in many of the programs, and has been the subject of widespread discussion between the members. There was very little opposition to the Dunmore bill and what there was seemed to center around the registration fee clause. To a great many of us, the failure of the Senate to act on the bill was a bitter disappointment.

Democrats and Republicans alike had to agree with the message sent the Senate in its closing hours by the Governor. All of us, however, are deeply grateful to the Legislative Committee for their untiring efforts towards the Dunmore bill and also for their efforts to prevent the passage of the various "cult" bills which came up during the session.

Respectfully submitted,  
GEORGE HENRY FOX,  
*President*

April 15, 1925

## REPORT OF THE COUNCILLOR OF THE SEVENTH DISTRICT BRANCH

### *To the House of Delegates*

I have attended meetings of Wayne County Society twice in the past year, at each meeting there was a good attendance and discussions were general. The younger men do not attend as faithfully as the older men. The membership committee and legislative committee were active and made good reports.

The Livingston County Society usually has a good attendance and last year they declared themselves in favor of the Medical Practice Act and the additional dues. While a small society they always have a good attendance and the scientific discussions are always of interest.

In Ontario County there is a very active

Geneva Hospital organization, which includes most of the county practitioners. They have most successful meetings with a very excellent showing of members and excellent discussions.

The other counties I have failed to meet with. The annual meeting of the Seventh District Branch was held at the Dansville Health Resort and was very successful from every point of view.

Although arrangements have not yet been made it is hoped to have our next district branch meeting at Auburn.

Respectfully submitted,  
WILLIAM I DEAN,  
*President*

April 15, 1925

## REPORT OF THE COUNCILLOR OF THE EIGHTH DISTRICT BRANCH

### *To the House of Delegates*

The morale of the Eighth District Branch is excellent and seems to be largely the result of more business-like methods of administration of the Society's affairs, as evidenced by the installation of an Executive Officer. There has been a prompt and favorable response from the various counties to the request for increased dues of the State Society, which augurs well for an aggressive future. An interesting experiment has

been the grouping of several counties in one meeting. This seems to have increased the interest and attendance.

The programs of several counties have been presented by the local members, which has proved valuable and a pleasing variation.

Respectfully submitted,  
HARRY R. TRICK,  
*President*

April 15, 1925

# HOUSE OF DELEGATES

The Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Hotel Syracuse, Syracuse, New York, Monday afternoon, May 11, 1925, at 2 o'clock, Speaker Dr E Eliot Harris presiding, Dr Edward Livingston Hunt, Secretary. The Speaker announced that the Secretary will call the roll by Counties for the purpose of determining the presence of recognized Delegates, a quorum being present the House is now organized for business.

## MEMORY, DR. W. DEWEY ELSEVER

The Speaker I wish to call your attention to an important matter. Dr W Dewey Elsever, Chairman of the Committee on Arrangements, and a member of the Council of this Society, long respected and beloved by his colleagues, within and beyond the boundaries of the City of Syracuse, died last December. I shall ask the House to rise and remain standing in silence one minute out of respect to the memory of Dr W Dewey Elsever.

Whereupon the House acted as requested.

The Speaker The first is the report of the Committee on Credentials, Dr Hunt, Chairman.

## COMMITTEE ON CREDENTIALS

Dr Hunt Mr Speaker, the report of the Committee on Credentials will be ready tomorrow.

The Speaker The next order of business is the calling of the roll by the Secretary, which will be deferred until tomorrow morning, unless there is some objection. There being none, it is so ordered.

The next is the reading of the minutes of the previous meeting. They have been published, and unless there is some additions or corrections they will stand approved as printed. There being none, they stand approved.

The next is the address of the President, Dr Owen Jones.

Dr Jones Mr Speaker, inasmuch as the report has been printed and is in the hands of all the delegates, I ask that the reading of the report be dispensed with.

The Speaker If there be no objection, the request of the president will be complied with. Hearing none it is so ordered.

The next is the address of the Speaker. As that has already been read—by some, I hope—it will be referred to the Committee on Speaker's Address.

The next is the report of the Committee on Council and Councillors. What is your pleasure, Gentlemen?

Dr Daniel S Dougherty, of New York.

I move that the balance of the printed reports be referred to their respective reference committees.

Motion seconded and carried.

The Speaker The Secretary will please read the names of the members of the reference committees.

## REFERENCE COMMITTEES

The Secretary read the following Reference Committee on the President's Address: Samuel J Kopetzky, New York, Chairman; Cornelius J Egan, Bronx; J Richard Kevin, Kings; Floyd S Winslow, Monroe; William H Purdy, Westchester.

Reference Committee on Speaker's Address: George A Leitner, Rockland, Chairman; Nelson O Brooks, Madison; Henry C Courten, Queens; Carl R Comstock, Saratoga; George E Welker, Yates.

Reference Committee on Reports of Council and Councillors: John E Jennings, Kings, Chairman; Robert W Andrews, Dutchess-Putnam; H Burton Doust, Onondaga; Luther C Payne, Sullivan; Edward W Weber, Westchester.

Reference Committee on Reports of Secretary and Treasurer: James Pedersen, New York, Chairman; Frank M Dyer, Broome; John L Edwards, Columbia; Peter L Harvie, Rensselaer; Robert M Elliott, Seneca.

Reference Committee on Report of the Committee on Scientific Work: Thomas C Chalmers, Queens, Chairman; William B Johnson, Cattaraugus; Henry S Paterson, New York; William A Peart, Niagara; LeRoy Becker, Schoharie.

Reference Committee on Report of the Committee on Legislation: George Kosmak, Chairman; Warren Wooden, Monroe; Robert L Barlett, Oneida; Homer J Kmckerbocker, Ontario; Luther Emerick, Ulster.

Reference Committee on Reports of Committee on Public Health and Medical Education: William H Ross, Suffolk, Chairman; Charles R Borzilleri, Erie; Edward M Cohe, New York; Zenas V D Orton, Washington.

Reference Committee on Report of the Committee on Medical Economics: W Warren Britt, Erie, Chairman; L Whittingham Gorham, Albany; J Lewis Amster, Bronx; Clarence J Whalen, Genesee; Charles R Kingslev, Richmond.

Reference Committee on Report of Special Committee on Nurses: Andrew Sloan, Oneida, Chairman; John A Card, Dutchess-Putnam; Le Rue Colegrove, Chemung; Charles A Gordon, Kings; Edward C Brenner, New York.

Reference Committee on Report of Legal Counsel: Terry M Townsend, New York, Chairman; Nathan B Van Etten, Bronx; Alton B Daley, Greene; Sidney F Blanchet, Franklin; Herbert B Smith, Steuben.

Reference Committee on New Business—A: W Francis Campbell, Kings, Chairman; Chauncey R Bowen, Allegany; Charles B Warner, Essex; George R Critchlow, Erie; Edward C Rushmore, Orange.

Reference Committee on New Business—B: James E Sadlier, Dutchess-Putnam, Chairman; Charles D Ver Nooy, Cortland; Murray M Gardner, Jefferson; E Warren Presley, Richmond; Jerome S Thomas, Queens.

Reference Committee on New Business—C: De Witt Stetten, New York, Chairman; Arthur M Dickinson, Albany; Allen W Holmes, Schuyler; William J Traci, Steuben; Arthur W Hubbard, Wyoming.

Reference Committee on Credentials: E. Livingston Hunt, New York, Chairman; Frank D Jennings, Kings; W Meddaugh Dunning, Bronx; Milton A Bridges, New York; Charles B Story, Queens.

The Speaker We have arrived at Unfinished Business. The matter of by-laws will be referred to Reference Committee A.

## FRAUDULENT PRACTICES (see page 805)

The Speaker We are now under New Business. Dr Dougherty, New York. Under this head New York County desires to present the following resolution: Whereas, there exists in the State of New York today a situation which menaces the public health and threatens to undermine public confidence in the legitimate practice of medicine, and

Whereas there are a large number of individuals and establishments actively opposing the best interests of the ill, the defective and the growing youth, through illegal, deceptive and fraudulent practices; and

Whereas, many of these individuals and establishments appear to be operating under a system of organized charlatanism, whose chief function is to obtain money from the unlettered, the uninformed, the alien and the ignorant through such frauds; and

Whereas, these conditions exist not only in every large city but in many of the small towns and villages

throughout the state, thereby making this problem an issue for the State Society.

Therefore, be it Resolved That the House of Delegates instruct the Council to properly investigate and take such measures as will correct these deplorable conditions.

The Speaker Referred to Reference Committee on New Business A

#### SECTION OF DERMATOLOGY (see page 804)

Dr Louis Tulipan, New York

At the request of the Dermatological staff of the College of Physicians and Surgeons, of the City of New York,

Resolved, that a section on Dermatology and Syphilology be established by the Medical Society of the State of New York.

The Speaker It will be referred to Reference Committee on New Business B

#### TITLE DOCTOR (see page 804)

Dr Dougherty, New York This resolution is introduced by New York County at the request of the New York Department of Health

Whereas, A person practices medicine, within the meaning of Article 8 Section 160, Paragraph 7 of Public Health Act, New York State, who holds himself out as being able to diagnose, treat, operate, or prescribe for any human disease, pain, injury, deformity, or physical condition, and who shall either offer or undertake by any means or method, to diagnose, treat, operate or prescribe, for any human disease, pain injury, deformity or physical condition

Whereas, There are persons using the title "Doctor" in connection with the practice of chiropody or podiatry. And Whereas, The use of the title "Doctor" is not authorized by any law or statute.

And Whereas, There is no statute forbidding the use of such a title, especially when used to deceive the public as to the person who pretends to practice medicine.

And Whereas, Chiropodists or Podiatrists are using the title of "Doctor" for the purpose of deceiving the public by holding themselves out as "Doctor of Medicine."

THEREFORE BE IT RESOLVED That the House of Delegates request the Council to institute legal proceedings to prohibit such unauthorized use of the title Doctor by those conducting an occupation involving or pertaining to the Public Health

The Speaker It will be referred to Reference Committee on New Business C.

#### CONTROL COUNTY SOCIETIES (see page 804)

Dr Orrin Sage Wightman, New York

Resolved that when any action has been taken by the House of Delegates of the Medical of the State of New York in session or by referendum vote by the component County Societies the majority vote so recorded shall determine the attitude of the County Societies, and that any public action or appearance of the individual County Society against the recorded opinion of the State Society's majority vote shall be a breach of Medical Ethics

This resolution is not meant to limit or prevent the expression of anyone's personal opinions or views

The Speaker Referred to Reference Committee on New Business A

Dr Dougherty New York offers the following resolution pursuant to a resolution adopted by the County Society and sent to the A. M. A.

Resolved, that the Medical Society of the State of New York, hereby invites the American Medical Association to hold its 1926 meeting in the City of New York

The Speaker Referred to Reference Committee on New Business B

#### MEDICAL PRACTICE BILL (see pages 812-815)

Dr Chalmers, Queens

Resolved that the Council of the Medical Society of the State of New York be and is hereby instructed to prepare such amendments to the Medical Practice Act as may tend to strengthen the practice of medicine and safeguard the people of the State against illegal practice, and that such amendments shall exclude any provisions requiring re-registration of physicians now in practice or hereafter registered under existing laws and that the bill shall be published in the New York State Journal of Medicine not later than October 1, 1925, and for discussion shall be afforded the columns of the Journal. The Council shall prepare and complete, not later than December 15, 1925 a Referendum, through the mail, to the House of Delegates and procure the introduction of such measure in the Legislature, it approved by a majority of such Delegates voting thereon

The Speaker It will be referred to the reference Committee on Legislation.

#### VOLSTEAD ACT (see page 805)

Dr Chalmers Whereas certain provisions of the Volstead Act and Acts amendatory thereto prohibit, without exception or qualifications, physicians from prescribing more than one pint of spirituous liquor to any patient in ten days, and

Whereas, at a meeting of the House of Delegates of the American Medical Association resolutions were adopted condemnatory of such provisions, and advocating a change in the law and the adoption of proper regulations by the Prohibition Department and the Internal Revenue Commissioners, and

Whereas at the time of the passage of the Volstead Act Regulations, as distinguished from Prohibition could have adequately dealt with the subject and yet have left unimpaired the rights and obligations of physicians to prescribe spirituous liquor for their patients when in their best judgment required, and at the same time have prevented the unworthy practitioner from prescribing liquors for beverage purposes under the guise of legitimate prescriptions, and

Whereas, regulations to that end could still be formulated and promulgated in case such provisions of the said Acts be declared unconstitutional, and should be prepared without further delay, and

Whereas, the present prohibitions have operated mainly to prevent large numbers of physicians of standing and professional integrity from prescribing for their patients in accordance with their best judgment as to their patients' necessities, while the unlawful acts of the unworthy practitioners have been promoted, and the further effect of such prohibitions has been that liquor of standard quality, necessary for medicinal prescription purposes has largely become unprocurable, it is hereby

Resolved, in view of the fact that such portions of the Volstead Act and the Amendatory Acts may be declared unconstitutional that, as a substitute therefor, regulations should be forthwith drafted by the Prohibition Department to the end that the present abuses may be abated, and existing prohibitions as to the practice of medicine removed, and that this Association use all means within its power looking to the preliminary approval of such regulations by the Prohibition Department and the Commissioner of Internal Revenue

In view of the fact that this resolution has a bearing on the suit of the Association of Constitutional Rights (Prohibition Com vs Samuel Lambert) we recommend that this Resolution be forwarded to American Medical Association with the unanimous approval of the House of Delegates

The Speaker The Resolution will be referred to Reference Committee on New Business C

## AMENDMENTS TO CONSTITUTION

Dr Wightman, New York I would like to offer three amendments to the Constitution

*Article IV Council*

Amended to read

The Council shall be composed of

(a) officers of the Society (strike out the word "except" and place instead the word "including") the assistant Secretary and assistant Treasurer

(b) Chairman of the Standing Committees add (including Editor-in-Chief of the State Journal)

*Article V* The officers of the Society shall be a President (add) a President-Elect, etc

To (d) the past Presidents (add) "and Secretaries who shall be life members with voice but without vote."

The Speaker They will be placed on file, please hand them to the Secretary

## BUDGET (see pages 805-813)

Dr Goodrich, Kings Resolved, that the Treasurer of the Medical Society of the State of New York be instructed to place the finances of the Society on a budget basis, that after preparing a budget annually it be submitted to the Council for approval (with such modification as shall be deemed wise and prudent by the majority of the Council)—and that the dues recommended to the Society for each year be based precisely upon the requirements of said budget

The Speaker Referred to Reference Committee on New Business A

President Jones I have here a communication in regard to the nursing question I ask that it may be referred to the proper committee

The Speaker Do you wish it referred without reading?

Dr Jones Yes, it is too long to read

The Speaker The request of the President will be complied with, if there be no objection. The communication is received and referred to the Reference Committee on Nurses

Dr Jewett Kings I have a report here of the Committee on Nurses It has a number of suggestions as to the treatment of the situation as to Nurses

The Speaker If there be no objection it will be referred without reading to the Committee on Nurses There being none it is so ordered

Dr Gardner, Erie I wish to submit a report from the Erie County Society Committee on the Nurse Question I would like to submit their report without reading

The Speaker There being no objection, it is referred to the Reference Committee on Nurses

The Speaker If there are no other resolutions, it would be well to take a recess to give the committee time to do their work.

Upon motion, seconded and carried, a recess was declared at 245 P M

The meeting was called to order at 3 15 P M

The Speaker The Secretary will call the names of the Reference Committees, and ask if any are ready to report

## SECTION ON DERMATOLOGY (see page 803)

Dr Sadlier Reference Committee on New Business B recommends the adoption of the resolution of Dr Louis Tulipan, Delegate from the County of New York, relating to the establishment of a section on Dermatology and Syphilology

Seconded and carried

## INVITATION TO A M A (see page 803)

Dr Sadlier Reference Committee on New Business B recommends the adoption of Dr Dougherty's resolution that the Medical Society of the State of New York invite the American Medical Association to hold its 1926 meeting in the City of New York

I move its adoption

Seconded and carried

## TITLE DOCTOR (see page 803)

Dr Stetten Reference Committee on New Business C approves the Resolution introduced by Dr Hubbard of New York for the New York City Department of Health, in regard to the illegal use of the title "Doctor" by chiropodists or podiatrists, and recommend its adoption by the House of Delegates

Seconded and carried

The Speaker Is there any other reference committee ready to report?

## SPEAKER'S ADDRESS

Dr Leitner, Reference Committee on Speaker's Address

We approve of each and every recommendation made by our Speaker, with the single exception of the one referring to the bestowal of the honorary title of General Supervisor of the Medical Society of the State of New York, upon Miss Lily D Baldwin, and our committee respectfully recommends to the council in its stead the bestowal of an honorarium of Five hundred dollars as an appreciation of the splendid and efficient work done by her for the Medical Society of the State of New York during the past twenty-five years

It was moved and seconded that the report be adopted. Carried unanimously

## CONTROL OVER COUNTY SOCIETIES (see page 808)

Dr Campbell, Chairman Reference Committee on New Business A

'Resolved that when any action has been taken by the House of Delegates of the Medical Society of the State of New York in session or by a referendum vote by the component County Societies, the majority vote so recorded shall determine the attitude of the County Societies, and that any public action or appearance of the individual County Society against the recorded opinion of the State Society's majority vote shall be a breach of Medical Ethics

This resolution is not meant to limit or prevent the expression of anyone's personal opinions or views"

Since it is highly advisable that the Society shall appear before the public and the State Legislature as holding an undivided opinion on matters pertaining to the profession's welfare, your committee recommends the adoption of this resolution

Seconded.

Dr Kevin, Kings I move that we lay this on the table

Seconded

Upon a rising vote the motion was declared lost.

Dr Kevin I arise to a point of order as to whether the resolution is not inconsistent with the constitution and by-laws of the State Society

The Speaker The point of order is not well taken

Dr Frank D Jennings, Kings I rise to a point of information, Mr Speaker May I assume a hypothetical case?

The Speaker Provided it has direct relation to the subject under discussion

Dr Jennings It will, sir, that a given piece of legislation is before the State Legislature, and that my County Society delegates me to talk at a public forum in Brooklyn in opposition to the measure, that the House of Delegates has acted favorably upon it, would I be guilty of a breach of ethics?

The Speaker I am perfectly willing that the Delegate from Kings County should discuss a hypothetical question in relation to the question before the House, but he should not demand a hasty opinion of the Speaker as to the correctness of what he states hypothetically or if it would be a breach of ethics This question of ethics requires considerable thought Even the learned legal counsel at times takes things under consideration before rendering a decision

Dr Jennings In view of that, Mr Speaker and in view of the rather close decision, I move that the question be referred back to the committee

Seconded, and carried

VOLSTEAD ACT (see page 803)

Dr Campbell The report of your committee on the Resolution introduced by Dr Chalmers, concerning the Volstead Act, is as follows In view of the fact that this resolution has a bearing on the suit of the Association of Constitutional Rights (Prohibition Com vs Samuel Lambert), we recommend that this Resolution be forwarded to A M A with the unanimous approval of this House of Delegates"

I move its adoption

Seconded, and carried unanimously

FRAUDULENT PRACTICES (see page 802)

Dr Campbell

Whereas, there exists in the State of New York today, a situation which menaces the public health and threatens to undermine public confidence in the legitimate practice of medicine, and,

Whereas, there are a large number of individuals and establishments actively opposing the best interests of the ill, the defective, and the growing youth, through illegal, deceptive and fraudulent practices, and

Whereas, many of these individuals and establishments appear to be operating under a system of organized charlatantry whose chief function is to obtain money from the unlettered, the uninformed, the alien and the ignorant through such frauds, and

Whereas, the conditions exist not only in every large city but in many of the small towns and villages throughout the state thereby making this problem an issue for the State Society

THEREFORE BE IT RESOLVED That the House of Delegates instruct the Council to properly investigate and take such measures as will correct these deplorable conditions"

Your Committee recommend the endorsement of this resolution.

Seconded, and carried

BUDGET (see page 804)

Dr Campbell Resolved that the Treasurer of the Medical Society of the State of New York be instructed to place the finances of the Society on a budget basis, that after preparing a budget annually he submit this to the Council for approval with such modifications as shall be deemed wise and prudent by the majority of the Council—and that the dues recommended to the Society for each year be based precisely upon the requirements of the budget."

I have the honor to report, Mr Speaker, that a majority of the committee make the following report,—

The Speaker The majority is the report of the committee, and therefore you are reporting for the committee.

Dr Campbell Your committee is in favor of the submission by the Council of an annual budget We question, however, the wisdom of basing the annual dues upon such a budget. We believe that the uncertainty of the amount of dues to be collected each year, as the result of such a proposed procedure, would have an unfavorable effect upon the membership of the Society, present and prospective

I also ask permission of the House to make a minority report,

The Speaker It is rather unusual for a chairman to make a majority and also a minority report of his committee, but in order to get the statement of the minority of the committee before the House it is necessary to have the consent of the House to receive it. It is generally given. All those in favor of receiving the minority report say aye, opposed no

Motion carried

Dr Campbell The minority report states that since there is no reason for the State Society to accumulate funds for sinking fund or other purposes, the dues should be based upon the requirements of the Council's budget,

and thus relieve the County Societies of any extra dues beyond the requirements of the State budget.

Dr Kopetzky, New York. I move the adoption of the majority report.

The Speaker That is the only one before you

Motion seconded

Dr Ludlum, Kings I rise to a point of order I think that Article 8 of the by-laws determines the way in which the decision as to annual dues shall finally be made, regardless of advice given that way, and any change must be made by modification of the by-laws

The Speaker The point of order as applying to a report of a committee is not well taken All those in favor of the report of the committee say aye, those opposed say no The chair is in doubt

Upon a rising vote the motion was carried

The Vice Speaker takes the chair

PRESIDENT'S ADDRESS

Dr Kopetzky The Committee on President's Address is ready to report. Your committee has read and considered the report of the President and finds that his modest report does not do justice to the amount of time and energy and constructive thought which he has given to his duties and the Committee congratulates the Society on the state of its affairs as reported by the President and feels that the Medical Society of the State of New York but inadequately expresses its appreciation of his endeavors by thanking him officially for his work.

In regard to his recommendations we will take them up in detail

JOURNAL PUBLICATION

First —We approve and recommend for adoption that the journal of the State Society should be published semi-monthly throughout the year, providing sufficient funds are available, except during the session of the Legislature, when it shall be published weekly as was the custom in the past two years Your Committee feels that while approving this recommendation they would urge that measures be taken to publish the journal weekly throughout the year, as the increased income from advertising would more than warrant the slightly additional expense, if there be any

That is the first recommendation

The Vice Speaker Gentlemen, what is your pleasure as to the report?

Dr Dougherty A point of information, is this a matter for the House of Delegates, or is it a matter for the Council, as it carries with it the expenditure of money?

The Vice Speaker It is a matter for the Council

Dr Kopetzky This recommendation carries no appropriation, and therefore there is no question for the Council It is a question of the House of Delegates approving the recommendation of the President of the Society which we do

Dr O'Reilly, Kings A point of information If this resolution carries no provision for the expenditure of money, who will take care of the deficit?

The Vice Speaker It is a matter entirely for the Council Dr O'Reilly

Dr Dougherty You having declared it a matter for the Council to decide, it is a matter entirely out of the hands of this body

The Vice Speaker The report carries no appropriation, you are voting on the recommendation of the President No appropriation is carried with this whatever

A Delegate If the paper is issued oftener than it is at the presentation time, whether this report carries an appropriation or not, there will be expense connected with it

The Vice Speaker That is a matter entirely up to the Council.

The Delegate Then we cannot act on it, can we?

The Vice Speaker You can act on the suggestion but you cannot act on the appropriation.

Upon being submitted to a rising vote, the motion was carried

## AMENDMENTS TO CONSTITUTION

Dr Wightman, New York I would like to offer three amendments to the Constitution

*Article IV Council*

Amended to read

The Council shall be composed of

(a) officers of the Society (strike out the word "except" and place instead the word "including") the assistant Secretary and assistant Treasurer

(b) Chairman of the Standing Committees add (including Editor-in-Chief of the State Journal)

*Article V* The officers of the Society shall be a President (add) a President-Elect, etc

To (d) the past Presidents (add) "and Secretaries who shall be life members with voice but without vote."

The Speaker They will be placed on file, please hand them to the Secretary

## BUDGET (see pages 805-813)

Dr Goodrich, Kings Resolved, that the Treasurer of the Medical Society of the State of New York be instructed to place the finances of the Society on a budget basis, that after preparing a budget annually it be submitted to the Council for approval (with such modification as shall be deemed wise and prudent by the majority of the Council)—and that the dues recommended to the Society for each year be based precisely upon the requirements of said budget

The Speaker Referred to Reference Committee on New Business A

President Jones I have here a communication in regard to the nursing question I ask that it may be referred to the proper committee

The Speaker Do you wish it referred without reading?

Dr Jones Yes, it is too long to read

The Speaker The request of the President will be complied with, if there be no objection The communication is received and referred to the Reference Committee on Nurses

Dr Jewett, Kings I have a report here of the Committee on Nurses It has a number of suggestions as to the treatment of the situation as to Nurses

The Speaker If there be no objection it will be referred without reading to the Committee on Nurses There being none it is so ordered

Dr Gardner, Erie I wish to submit a report from the Erie County Society Committee on the Nurse Question I would like to submit their report without reading

The Speaker There being no objection, it is referred to the Reference Committee on Nurses

The Speaker If there are no other resolutions, it would be well to take a recess to give the committee time to do their work

Upon motion, seconded and carried, a recess was declared at 2 45 P M

The meeting was called to order at 3 15 P M

The Speaker The Secretary will call the names of the Reference Committees, and ask if any are ready to report

## SECTION ON DERMATOLOGY (see page 803)

Dr Sadler Reference Committee on New Business B recommends the adoption of the resolution of Dr Louis Tulpan, Delegate from the County of New York, relating to the establishment of a section on Dermatology and Syphilology

Seconded and carried

## INVITATION TO A. M. A. (see page 803)

Dr Sadler Reference Committee on New Business B recommends the adoption of Dr Dougherty's resolution that the Medical Society of the State of New York invite the American Medical Association to hold its 1926 meeting in the City of New York.

I move its adoption

Seconded and carried

## TITLE DOCTOR (see page 803)

Dr Statton Reference Committee on New Business C approves the Resolution introduced by Dr Hubbard of New York for the New York City Department of Health, in regard to the illegal use of the title "Doctor" by chiropodists or podiatrists, and recommend its adoption by the House of Delegates

Seconded and carried

The Speaker Is there any other reference committee ready to report?

## SPEAKER'S ADDRESS

Dr Leitner, Reference Committee on Speaker's Address

We approve of each and every recommendation made by our Speaker, with the single exception of the one referring to the bestowal of the honorary title of General Supervisor of the Medical Society of the State of New York, upon Miss Lily D Baldwin, and our committee respectfully recommends to the council in its stead the bestowal of an honorarium of Five hundred dollars as an appreciation of the splendid and efficient work done by her for the Medical Society of the State of New York during the past twenty-five years.

It was moved and seconded that the report be adopted. Carried unanimously

## CONTROL OVER COUNTY SOCIETIES (see page 808)

Dr Campbell, Chairman Reference Committee on New Business A

'Resolved that when any action has been taken by the House of Delegates of the Medical Society of the State of New York in session or by a referendum vote by the component County Societies, the majority vote so recorded shall determine the attitude of the County Societies, and that any public action or appearance of the individual County Society against the recorded opinion of the State Society's majority vote shall be a breach of Medical Ethics

This resolution is not meant to limit or prevent the expression of anyone's personal opinions or views"

Since it is highly advisable that the Society shall appear before the public and the State Legislature as holding an undivided opinion on matters pertaining to the profession's welfare, your committee recommends the adoption of this resolution

Seconded.

Dr Kevin, Kings I move that we lay this on the table. Seconded

Upon a rising vote the motion was declared lost

Dr Kevin I arise to a point of order as to whether the resolution is not inconsistent with the constitution and by-laws of the State Society

The Speaker The point of order is not well taken

Dr Frank D Jennings, Kings I rise to a point of information, Mr Speaker May I assume a hypothetical case?

The Speaker Provided it has direct relation to the subject under discussion

Dr Jennings It will, sir, that a given piece of legislation is before the State Legislature, and that my County Society delegates me to talk at a public forum in Brooklyn in opposition to the measure, that the House of Delegates has acted favorably upon it, would I be guilty of a breach of ethics?

The Speaker I am perfectly willing that the Delegate from Kings County should discuss a hypothetical question in relation to the question before the House, but he should not demand a hasty opinion of the Speaker as to the correctness of what he states hypothetically or if it would be a breach of ethics This question of ethics requires considerable thought Even the learned legal counsel at times takes things under consideration before rendering a decision

Dr Jennings In view of that, Mr Speaker and in view of the rather close decision, I move that the question be referred back to the committee

Seconded, and carried

our Constitution and By-Laws to carry into effect the above recommendations."

It is necessary if we want to adopt this form of government that the Legislature of the State of New York pass an enabling act, and this recommendation instructs Mr George Whiteside, our Counsel to prepare such an enabling act so that we shall be able to adopt these proposed changes in our constitution at our next annual session of the House of Delegates. I move the adoption of the resolution

Seconded.

Dr Ludlum, Kings It seems to me that this is such an important and grave matter that it should receive very careful consideration. If this enabling act is passed the presumption is that the rest of the matter is to prevail. I am in no position of opposition or concord with the act at the present time, I am simply emphasizing its importance. I presume it is in order for any one or any group of us to put a recommendation for a change of the Constitution or By-laws on the record so that it can be acted upon next year. It seems to me that inasmuch as we have a committee on Revision of Constitution and By-laws that the best immediate action to take would be to refer the whole matter, including the recommendation, to the Committee on Revision of Constitution and By-laws, for their consideration.

Dr Dougherty I am heartily in favor of all that has been read on the subject by Dr Kopetzky, and I would like to express my opinion that their work in drawing up this drafted amendment is highly commendable, but there is just one thing we have to think of, I consulted with Dr Harris, our Speaker some time ago regarding this with the idea of drawing up such an amendment, and I was informed that Mr Whiteside was working on the matter, and that it could not be received until he had decided whether we could consider even the reception of such amendments before the enabling act. I would like to ask the Speaker if Mr Whiteside has expressed his opinion as to that?

The Vice Speaker Is Mr Whiteside in the room?

Mr Oliver May I answer for Mr Whiteside? Mr Whiteside has expressed the opinion that there could be received at this meeting of the House of Delegates the proposed amendment to be acted upon at the meeting of 1926, if and when the Legislature authorize by an enabling act a change in the Constitution and By-Laws of the Society.

Mr Dougherty Then should not the words be inserted in it?

Dr Ward B Hoag, New York This says that George W Whiteside shall pave the way for the approval of this. Suppose something happens to Mr George W Whiteside, where will that leave the proposed changes?

The Vice Speaker Mr Whiteside's office will take care of it.

Dr Dougherty I move that the debate on this question be closed, as all the speakers have been out of order.

The Vice Speaker Are you ready for the question?

Dr Lasher I rise to a point of order. Is this discussion is out of order, the vote is out of order.

The Vice Speaker Those in favor of the report of the Committee will say aye, opposed, no carried.

Dr Lasher I appeal the decision of the Chair on the point of order by me.

The Vice Speaker I rule against it. It is too late to appeal after the vote has been taken.

The Speaker takes the chair.

#### COMMITTEE ON SCIENTIFIC WORK

Dr Chalmers Your Reference Committee on Scientific Work has the honor to report that it desires to particularly commend the scheme of the scientific program for this year's convention whereby Thursday, May 14th,

is devoted to a complete consideration of tuberculosis in all its aspects and believes this practice furnishes a promising precedent for future programs. The program in general sets a high standard of excellence.

The reference Committee unanimously voted to endorse the recommendation that each section elect its secretary for three years and voted further to endorse the recommendation that the actual expenses of program guests from out of the State be paid by the Society together with the expenses of any necessary laboratory assistant not in practice.

#### POST-GRADUATE MEDICAL INSTRUCTION

The Reference Committee desire to commend in the highest terms the report of the Committee on Post Graduate Medical Instruction and endorse the recommendation contained therein that "a special committee be appointed with power to put into immediate effect a plan of graduate medical extension instruction which will meet the greatest need to-day."

The reference Committee further suggests that it shall be the duty of this special committee to coordinate the existing medical schools and hospital staffs according to their geographical zone to the end that in and around each may be created a center for post-graduate medical education, with which adjacent country societies shall cooperate in every way possible.

I move its adoption.

Seconded and carried.

#### REPORT OF COUNCIL AND COUNCILLORS

Dr John E Jennings Your Committee on the Report of Council and Councillors recommends the acceptance of the report of the Council but calls attention to the neglect of Council to comply with the spirit of the recommendation of the House of Delegates in adopting the report and recommendation of Reference Committee C at the annual meeting of the House of Delegates held in Rochester in 1924 namely, that such amendments to the Public Health Law as are necessary be formulated by the Council and by them referred for approval by referendum sent by mail to the House of Delegates.

The action of the Council on February 18, 1925, approving measures already before the Legislature and ordering a referendum of the House of Delegates on its approval is not deemed a full compliance with the recommendations of the House of Delegates.

The Committee recommends the adoption of the reports of the Councillors of the third, fifth, sixth, seventh and eighth district branches, but calls attention to the neglect of the Councillors of the first, second and fourth district branches to submit reports."

I recommend its adoption.

Seconded.

Dr Kopetzky I do not think this House of Delegates understands that the adopting of that Committee's report carries with it a censure. I cannot conceive that the members of the Council will sit here without a word and hear the gentlemen censured without getting up and saying a word for themselves. I think it is no more than right that some member of the Council get up and explain his action, because I should hesitate to vote for censure of men who have devoted so much time to the interests of this Society, through a lack of an understanding of their action. May I ask that some member of the Council explain his action in the matter?

The Speaker Dr Kopetzky has asked some member of the Council to speak in explanation of that part of the report which he considers censures the Council.

Dr Kopetzky A point of information. Did the Council exceed its authority under the Constitution and By-Laws or did they comply with the Constitution and By-Laws in ordering this referendum?

The Speaker I should answer that they did not exceed their authority.

## PRESIDENT ELECT

Dr Kopetzky Second, the Committee approves and recommends the adoption of changes in the constitution and by-laws to provide for the office of "a President-elect" and submits the following amendments to the By-laws to cover the recommendations

That the Constitution be amended as follows

Article 5 Line 1, after the word 'President', insert the word 'President-elect'

## BOARD OF TRUSTEES

Dr Kopetzky Your Committee feels that the President's recommendation that the Society provide itself with a Board of Trustees whose duties it will be to study the needs and guide the control of the expenditures of the Society is indeed not only a well thought out recommendation, but a necessity if this Society is to function efficiently and without a waste of its funds, and we heartily approve this recommendation and in pursuance therewith we propose the following amendments to the Constitution and By-laws

## CONSTITUTION

Article V—Line 5, before the word "and" insert the words "five trustees"

Line 8, after the sentence ending with the word "years" insert the sentence "One trustee shall be elected annually to serve for a period of five years"

Article VIII, Line 9, strike out the word "Council" insert the words, "Board of Trustees"

Line 13, strike out the word "Council" and insert the words, "Board of Trustees"

## BY-LAWS

Sec 6, line 4, after the semi-colon (,) insert the words "(c) the Trustees", strike out the letter (c) and insert the letter (d)

Line 5 strike out the letter (d) and insert the letter (e)

Sec. 12, after line 12, insert a new line 13 to read "Report of the Trustees"

In the eight lines following change the numbers 8 to 15, inclusive, to read 9 to 16 inclusive

Sec 13 after the word "Officers" insert the word "Trustees"

Line 9, before the word "Chairman" insert the word "Trustees"

Sec 14, line 3, before the word 'censors' insert the word "Trustees"

After Sec 19, insert the following new sections

Section 20 At the first meeting of the Board of Trustees following the annual meeting of the House of Delegates, it shall organize and elect the Chairman The Board of Trustees shall hold regular meetings at times and places that shall be fixed by the Chairman, and any three members of the Board of Trustees may require the Chairman thereof to call a meeting for such time and place as shall be designated by them in writing of which the members of the Board shall have at least 2 days' notice

Section 21 The Board of Trustees shall have charge of all property and manage the financial affairs of the Society The budget prepared by the executive committee shall be submitted to the Board for its approval and all resolutions or recommendations of the House of Delegates or Council pertaining to the expenditures of money must be approved by the Board of Trustees before the same shall become effective

Section 22 All moneys of the Society received by the Board of Trustees, Council or any member or agent thereof shall be paid to the Treasurer of the Society The Board of Trustees shall approve the bond of the Treasurer as to amount, form and surety it shall employ a public accountant to audit the accounts of the Treasurer and Secretary and other agents of the Society and present a statement of the same in its annual report to the House of Delegates The Board of Trustees shall

make a report to the House of Delegates of its transactions for the year and of the amount of money belonging to the Society under its control

Section 23 Three (3) Members of the Board of Trustees shall constitute a quorum

Section 24 The following shall be the order of business at meetings of the Board of Trustees

1 Calling the meeting to order

2 Roll call

3 Reading of minutes

4 Communications

5 Reports

6 Unfinished business

7 New business

Section 25 In case of any vacancy on the Board of Trustees through death, resignation, disqualification, or other cause, the President shall appoint a successor to fill such vacancy until the next meeting of the House of Delegates

Section 26 At the annual session of the Society held in the year 1926, five (5) Trustees shall be elected by the House of Delegates They shall divide themselves according to their tenure of office, to wit, one to serve for five (5) years, one to serve for four (4) years one to serve for three (3) years, one to serve for two (2) years, and one to serve for one (1) year Thereafter, one shall be elected to serve for five years at each annual meeting

Sec. 20, line 1, change the number 20 to "27"

Sec 21, line 1 change the number 21 to "28"

Sec 22, line 1, change the number 22 to "29"

Sec 23 line 1 change the number 23 to "30"

Sec. 23, line 2 strike out the word "shall", line 3, strike out the entire line, line 4, strike out the words *affairs of the society*

Sec. 24, line 1, change the number 24 to "31"

Sec. 25, strike out the entire section

Sec 26, line 1, change the number 26 to "32"

In all succeeding sections change the number of the section

Sec 28, last line, strike out the word "council" and insert the words "Board of Trustees"

Sec 33, line 3, after the word "of" insert the words "The Board of Trustees and of"

After Section 33, insert a new section to be known as Section 40 which shall read

"Sec 40 The President-Elect shall assist the President in the performance of his duties"

Sec 37, line 3, after the word "Council" insert the words, "the Board of Trustees"

Line 35, strike out the word "Council" and insert the words "Board of Trustees"

Sec. 39 lines 4 and 5, strike out the words "Council or the Executive Committee," and insert the words "Board of Trustees"

Line 14, strike out the word "Council" and insert the words "Board of Trustees"

Last line, strike out the word "Council" and insert the words "Board of Trustees"

Sec 42 line 9, after the word "Council," insert the words, "of the Board of Trustees"

Lines 13 and 14, strike out the words *Executive Committee* and insert the words "Board of Trustees"

Line 23 strike out the words *Executive Committee* and insert the words "Board of Trustees"

Line 30 strike out the words *Executive Committee*, and insert the words "Board of Trustees"

Line 34, strike out the words *Council or Executive Committee* and insert the words "Board of Trustees"

Sec. 66 line 4 after the word "Council," insert the words "Board of Trustees"

Your Committee recommends the adoption of the following resolution

## ENABLING ACT

Be it Resolved, that Mr George Whiteside the Council of the Society is hereby instructed to draft a bill for presentation to the Legislature to enable us to amend

Vol 25, No 17  
June, 1925

E. Willard, Catskill, W. R. Sitler, Suffern, James F. Morgan, Brooklyn, G. F. Blauvelt, Nyack, Walter B. Lindsay, Huntington  
Upon motion duly seconded the meeting adjourned to reconvene at eight o'clock in the evening

## EVENING SESSION, MONDAY, MAY 11, 1925

The meeting was called to order by the Speaker at 8:35 P M

### PRIZE ESSAYS

The Speaker We have the report of the Committee on Prize Essays. It is a very short report, there being no essay worthy of the prize, and I ask general consent to suspend Sec. 90 of the By-Laws, in order that the report may be considered now. If there be no objection I shall consider it suspended by general consent, and so ordered.

"The Committee on Prize Essays begs leave to report that no prize was awarded this year. Only one essay was presented. That was a well worked out collection of statistics on a certain subject, but the deductions from them did not seem to the Committee, at least, to be entirely warrantable or worthy of a prize.

Respectfully submitted,

LUCIEN HOWE,  
FREDERIC C. CURTIS, "  
THOMAS H. CURTIN "

The Speaker The report will be received and placed on file.

### LEGAL COUNSEL

'Your Committee of Reference on the Report of Counsel for the period from March 1st, 1924 to April 1st, 1925, has the honor to submit the following report

Your Committee feels that the congratulations and thanks of this body should be tendered to the Counsel upon his success in disposing of one hundred and twenty-nine cases without loss of a single case.

The Counsel's educational propaganda as evidenced in his editorial comments in the Society's Journal as well as his constant interest and vigilance in protecting the laity from impositions of charlatans and irregular practitioners is highly commendable and deserves the official recognition of this body. The Counsel's associate, Mr. Robert Oliver, has rendered excellent service to the State Society in his unswerving fidelity to his chief and his presentation of matters of valuable legal information at meetings of various medical societies.

Your Committee seconds the Counsel's expression of appreciation of Mr. Harry F. Wanvig, the Authorized Representative of the Society, whose time is exclusively given to the administration of the details of the Group Insurance Plan of the Society.

Your Committee strongly endorses the Counsel's advice with reference to the rights and privileges of uninsured members. It recommends without reservation the prompt consideration and affirmative action of this body on the resolutions as outlined by Counsel in the closing paragraphs of his report. Your Committee further recommends that if adopted, a copy of these resolutions be placed in the hands of each member of the State Society.

Your Committee heartily endorses his final recommendations relative to investigation by local committees and report to the Counsel through the presidents of the and county societies the underlying causes of bringing malpractice suits against physicians. Your Committee further recommends that steps be taken to discourage bringing of such groundless suits or detrimental publicity concerning same before judgment has been entered, and, further, that any physician who stimulates a groundless action for malpractice against another physician whereby unjust injury to the accused's professional

standing and reputation may result—whether such action be actuated by unworthy rivalry or jealousy or may be the result of carelessness or thoughtless criticism—should be condemned for unethical and unfair practice and should be subjected to adequate discipline for such offense.

Moved and seconded, that the report be unanimously adopted. Carried.  
Dr Kosmak, New York

### COMMITTEE ON LEGISLATION

Your Reference Committee appointed to consider the report of the Committee on Legislation begs leave to submit the following for your consideration.

We desire to commend the Committee on Legislation of the State Society for its continued devotion to the duties imposed upon it, and especially commend its Chairman—Dr. James N. VanderVeer for his loyalty and untiring efforts for the welfare of the profession of the State.

We also recommend that appropriate expression of appreciation be forwarded by the Secretary of the Society to Governor Alfred E. Smith for his constant watchfulness and effort throughout the legislative and as well for his emergency message on the last day of the session urging that they report and pass the Karle-Dunmore Bill for the better protection of the people of this State. We also suggest a similar expression to be communicated to the other members of the Legislature mentioned in the report as deserving of similar recognition."

I move the adoption of this portion of the report

Seconded and carried.

Dr Kosmak We did not incorporate in our report the recommendations, and I think if we follow them in the printed circular that is sufficient.

### LEGISLATIVE BUREAU

Recommendation number one is approved, that the Legislative Bureau be continued, and a sufficient appropriation, under a budget system to be offered by the new chairman of the Committee on Legislation, be allowed.

I move its adoption

Seconded and carried.

### CONFERENCES COUNTY SOCIETY CHAIRMEN

Dr Kosmak Second, that provision be made for one or more conferences of county legislative chairmen, as in the past.

That recommendation is approved.

Seconded and carried.

### CO-OPERATION WITH SPECIAL SOCIETIES

Dr Kosmak Third, that some provision be made whereby your Committee on Legislation may cooperate with physicians who have grouped themselves into special societies, usually with community interest, some of whose members are not members of the State Society in legislative matters. I believe this will be spoken of in another report, but your committee on Legislation would recommend that the proper changes be made in our constitution and by-laws for some type of legislative representation of such societies is referred to the Council for action.

Seconded.

Dr Rooney I move as a substitute, that the question of authorization of the Committee on Legislation in securing the cooperation of various groups of physicians who are not affiliated with the Medical Society of the State Officially, be referred to the Council for their decision.

Seconded.

The Speaker All those who are in favor of the substitute offered by Dr Rooney will signify by saying aye.

Motion carried

Dr Kopetzky Did the Council fail to carry out any instructions of the House of Delegates?

The Speaker Not as far as I know if any of the instructions included an expenditure of money they were not in agreement with the Constitution and By-Laws, therefore not mandatory on the Council

Dr Rooney Mr Chairman, in order that we may hear from legal Counsel, I would move that we postpone discussion until the evening recess

Seconded, and carried

#### EDUCATION (see page 814)

Dr Critchlow, Reference Committee on New Business A, reports on the resolution presented by Dr Wightman

"Resolved, that when any action has been taken by the House of Delegates of the Medical Society of the State of New York in session or by a referendum vote by the component County Societies, the majority vote so recorded shall determine the attitude of the County Societies, and that any public action or appearance of the individual County Society against the recorded opinion of the State Society's majority vote shall be a breach of Medical Ethics

This resolution is not meant to limit or prevent the expression of anyone's personal opinions or views"

Your Committee is persuaded that the objects sought to be attained in this resolution are for the welfare of the Society as a whole, particularly where the legislative interests of the Society are concerned

We believe that the best interests of the Society will be conserved if all differences of opinion within the Society be allowed the freest discussion We believe also, however, that the legislative Committee should not be compelled to explain such difference of opinion to the State Legislature, thus giving the impression of a divided Society

We would earnestly appeal to all component county societies to loyally support all action that any be taken in any matter as determined by a majority vote of the House of Delegates

We would amend the resolution to read as follows

"Resolved that when any action has been taken by the House of Delegates of the Medical Society of the State of New York in session or by a referendum vote by the component county societies, the majority decision so recorded shall be morally binding on all county societies in their activities relating to state legislative matters"

Move the adoption and seconded.

Dr Wightman Might I say, Mr Speaker, that I accept that amendment in a spirit of co-operation

The Speaker It is moved and seconded that the amendment which is accepted by the mover and now becomes a part of his original resolution be adopted.

Motion carried.

#### COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION (see page 814)

Dr Ross, Chairman of Reference Committee on Public Health and Medical Education

The Committee on Scientific Work stole the thunder of this Committee's work. We will read it, and if they conflict you can reconcile them

The Report of the Committee on Public Health and Medical Education consists of suggestions for ten activities which might be considered by the State Medical Society The Reference Committee endorses all of these suggestions but especially emphasizes two of the subjects touched upon in the report Suggestions one and ten relate to periodic health examinations Your Committee endorses the movement and recommends that it be promoted in the pages of the Journal and by county societies

Suggestions four, six and seven relate to graduate medical education The Reference Committee recommends that the promotion of graduate medical educa-

tion be one of the major activities of the State Medical Society during the coming year The need and the desire for graduate medical education exists and it only awaits practical organization of method. There is abundant evidence of the truth of this statement in the result of evidence made in several States and Counties, notably Kings

In these times of rapid change of knowledge and practice there is need for some method of providing a steady stream of medical information to all sections away from medical centers as well as to make available to city practitioners the results of medical progress This work belongs to organized medicine.

Keeping every physician in the State fully informed as to advancing medical knowledge would be the most potent factor in the advancement of public health. The Reference Committee recommends that the House of Delegates authorize the Council to request the House of Delegates of the American Medical Association to cooperate with the Medical Society of the State of New York to the end that all available material for graduate medical instruction including teachers, charts, lantern slides, moving pictures, etc., be made available to the appropriate committee of the Medical Society of the State of New York for carrying out this plan and that the Council be authorized to appropriate as much money as they may deem expedient for the work of graduate medical instruction"

The Speaker It is moved and seconded that the report be adopted

Dr Phillips I feel that this House of Delegates should give a little more serious consideration to the report of the Committee in Public Health and Medical Education. Perhaps some of you are not aware that for several years the Council on Medical Education of the American Medical Association has been gradually developing a system of post graduate instruction and to make it available not only for states, but for counties, so that gradually there is being developed a system by which any state may apply to the American Medical Association and get the material, get the slides, get a great deal of help that would save enormous financial expense by the state or by the county, and in that way get before the smaller bodies from the constituent state and county societies the opportunity for medical education, and it is really post graduate instruction I would like if it could be done, to have this House of Delegates, in the line with this report, get it into some form so that you could go before the Council on Medical Education of the American Medical Association and make formal application that they enter into the work in conjunction with this state society in order that we might carry out a state wide system of work on post graduate medical education

The Speaker You could move to refer the report back to the Committee and have them incorporate some of the suggestions stated

Dr Phillips With this object in view I move that the matter be referred back to the Committee.

Seconded and carried

The Speaker It is so referred

#### RETIRED MEMBERSHIP

We have a number of applications for retired membership, and if there be no objection we will suspend section 90 of the By-laws, and consider them now It is so ordered.

The Secretary read the following applications for retired membership, and, upon motion duly made and seconded, each in turn was approved by the unanimous vote of the House

Miriam Gardner, Smyrna Arthur Middleton Jacobus, New York City, David F King, New York City, Walter E Lauderdale, Geneseo Archibald Lybolt, Bogot, N J, Constantine J McGuire, New York City, George W Miles, Oneida, Samuel Sherwell, Brooklyn, Charles

Vol 25 No 17  
June, 1925

The recommendation of your committee is that this matter be referred to the Council  
Seconded and carried  
Dr Kosmak Twelve

#### ATTITUDE ON BILLS

'12 That this House of Delegates discuss the old and familiar bills as to Birth Control, Anti-vivisection Child Experimentation, amendments to the Medical Practice Act, and place on the records of the House of Delegates what action shall be taken by the Committee on Legislation during the coming year so far as can be determined in the light of past legislation"

Dr Kosmak Number twelve is covered by reference to number ten, and approved by your Committee

The Speaker If there be no objection, the recommendation of the Chairman of the Committee will be adopted. Hearing none, it is adopted unanimously

Dr Kosmak Thirteen

#### MEDICAL ADVISOR BILL

"13 That this House of Delegates go on record as favoring a bill similar to Assemblyman Charles P. Miller's bill, A. Int. 1361, and direct your Committee on Legislation to confer with the County Legislative Chairman and legislators urging the passage of the same or some similar measure."

Number 13 is approved, provided that the nominating power is conferred upon the Council if the Legislation becomes effective

The subject matter of this recommendation is based upon the following paragraph in the report of the Committee

"Assemblyman Charles P. Miller of Genesee County introduced a bill amending the Workmen's Compensation law by providing for the appointment of a physician as Medical Advisor to be chosen from a list submitted by the Medical Society of the State of New York. This bill to a large degree would solve the crux of the conflict which has existed in the labor laws relative to medical attendance, judgment, supervision, advice to the industrial board, examination of fee bills examining physicians, employment of specialists, and the like."

The recommendation of your Reference Committee is that this recommendation be approved, provided that the nominating power is conferred upon the Council if the legislation becomes effective

Dr Frank Jennings I would like to inquire, through you, sir, of Dr Vander Veer, if I may, if that bill is the bill which provided that the medical advisor selected by the State Medical Society is to appoint his subordinates on salary? If so, the bill hasn't a Chinaman's chance. The bill is fallacious, if you will permit me to say so, in that it would permit a subordinate in a department to appoint subordinates under him, taking the appointing power away from the head of the department.

The Speaker Any further discussion? All in favor say aye, opposed no It is lost

Dr Kosmak Fourteen

#### NARCOTIC BILL

"14 That this House of Delegates approve or disapprove of the wording and legislative thought contained in the Kennedy-Wenfeld bill concerning habit-forming drugs"

Your committee approves this recommendation in accordance with the action of the House of Delegates of 1924

Dr Rooney I move as a substitute that the question of the approval or disapproval of any narcotic bill introduced in the Legislature of 1926 shall lie in the hands of the Council of the State Society

Seconded and carried

The Speaker The substitute has been approved, and is now before you as the main motion All those in favor say aye Opposed no Carried.

Dr Critchlow, of Erie I move you sir, a reconsideration of the action that was taken in regard to the previous recommendation of the Legislative committee

Seconded and carried

The Speaker The motion is carried and the question reconsidered is before you Any discussion upon number 13?

Dr Rongy, New York On a point of order I believe the entire motion to reconsider is out of order The report of the committee has not been accepted, and we cannot reconsider any part before the entire report is received

The Speaker The point of order is not well taken

Dr Rooney A point of information Is it possible for the Legislature to save to the Medical Society of the State of New York when one of these positions is open, that they shall not nominate the physician?

The Speaker The Chairman of the Committee will be glad to answer you

Dr Kosmak The nominations were to consist of three, from whom one was to be selected for this office, and the idea of the Reference Committee was that this nominating could be done more effectively by the Council than by any other means

Dr Rooney May I ask if the legal Counsel has been asked about that proposition?

Dr Phillips It strikes me that the nominating power would be the House of Delegates, and this House of Delegates can delegate that nominating power I see no reason why they cannot delegate that nominating power

Dr Rooney It is not a question as to which part of the Medical Society of the State of New York shall do the nominating, it is a question of a bill that delegates to the Medical Society of the State of New York the power of nominating to office a person who is a member of the State Department. It is just as though we were to delegate the power to some one outside of ourselves to nominate to office in the Society, and that seems to be the only point which militates against the bill

The Speaker That seems to be a legal question and I will call upon our legal Counsel to answer the legal questions involved

Mr Whiteside It seems to me the question is rather academic. At first you have to have the power before you discuss as to whether you can exercise it. I would suggest that we try it on and see whether we can do it I see no point in anticipating possible success or possible defeat. I think we should try and see whether or not this power can be exercised by this corporation, which is especially created by an act of legislation which has always been recognized as of a quasi-public character

The Speaker Are you ready for the question? All in favor say aye, opposed no Carried

Dr Kosmak Fifteen

#### CHOICE OF PHYSICIAN

"15 That this House of Delegates record itself as for or against the free choice of physicians by an injured workmen"

Recommendation number fifteen is approved, with the recommendation that the House of Delegates, record itself as "for" the free choice of physician.

Seconded and carried.

Dr Kosmak Sixteen

#### COMMITTEE ON WORKMEN'S COMPENSATION LAW

"16 That the Committee which was appointed to study the Workmen's Compensation Law be continued or a similar committee be appointed, and that they be directed to place in the hands of the Counsel their recommendations for amendments to the Workmen's Compensation Law in relation to the medical features thereof by September 1st, 1925 in order that the Counsel may draft the proper bills for introduction, and sub-

The Speaker The substitute which has just been carried becomes the original motion.

Seconded and carried  
Dr Kosmak Fourth

#### EXECUTIVE EDITOR

That your Executive Editor be directed to come to Albany during the legislative session and spend one or more days in Albany each week at the expense of the Society, thus becoming more familiar with legislative matters and being able the more to edit legislative articles for the benefit of the Journal

Seconded and carried  
Dr Kosmak Five

#### EDUCATION OF THE PUBLIC

'5 As before, we again recommend a broad dissemination of education on public health questions through the public press by means of someone of the adjunct committees of the State Society—thus laying a better foundation for the legislation which may come up, and would respectfully suggest (a) That the Journal of the State Society be sent during the Legislative season to all the legislators, to the newspapers published in this State, to the officers and members of the Executive Committees of the allied professions, State or District Societies of nurses, dentists, school medical inspectors, health officers' associations and the like, and to a selected group of lay societies (b) That conferences be held in the Council of the Society as to certain other selected medical and educative publications which should be sent to these groups

The Committee approves that recommendation

Dr Phillips It is going to involve a question of considerable expenditure of money, and I do not think we have a right to make that recommendation as a body I think it should be referred to the Council, and I move as a substitute that this recommendation be referred to the Council

Motion to refer to the Council

Seconded and carried  
Dr Kosmak Six

#### PHYSICIANS APPEARING WITHOUT CONSULTING COMMITTEE ON LEGISLATION

6 We would again recommend that the same rule be adopted in relation to physicians—members of the State Society—appearing before Committees of the Legislature without first consulting with the Chairman of the Committee on Legislation

This recommendation is approved by the committee

Seconded and carried  
Dr Kosmak Seven

#### MEET LEGISLATORS

7 That the County Societies be urged to meet with their legislators in the fall or at some convenient time in a social way and that it be obligatory on the County Society to so report to the Council or Committee on Legislation since much good has come from the meetings so held by many County Societies but, unfortunately, the reports of such meetings only reach the Legislative Bureau in a roundabout way

The Committee approves of that recommendation

Seconded and carried  
Dr Kosmak Eight

#### PROPOSING LEGISLATION

"8 That legislation which is sought by County Societies and individual members be sent in to the Bureau in the early Fall, so that the Counsel of the Society may draw up in proper form such legislation and submit it to the Council and Committee on Legislation before the opening of the session and that any Legislative suggestion or thought within or by a County Society shall

be in the hands of the Council for approval or disapproval not later than September 1st, 1925

Moved and seconded

That recommendation No 8 be adopted

Dr O'Reilly I would like to offer an amendment to that, Mr Speaker, that these communications from County Societies be in the possession of Council not later than July and that they be printed in the Journal not later than September 1, and that the columns of the Journal be open to a full discussion on the merits and demerits

Dr Kopetzky, New York I move that the amendment presented by Dr O'Reilly be laid on the table

The Speaker If it doesn't include the main question I must declare your motion out of order When a motion is laid on the table every motion adhering to it goes with it. Is there any further discussion? If not we will now vote on the amendment offered by Dr O'Reilly The amendment is lost. We will now vote upon the original motion of the chairman of the committee Carried

Dr Kosmak Nine.

#### ADVISORY COMMITTEE

"9 That the Council of the Society be directed to form some type of Advisory Committee of the profession of this State which shall eventually become an Advisory Council to governmental officers or departments when advice is so sought, since in many instances some physicians in private meetings with legislators hold themselves out to be representatives of many of these bodies and would convey to the individual legislators the thought of their importance of position, thus negating the efforts of the duly accredited officers of the various and individual professional societies This does not work for a harmonious entity in matters of public health legislation but by such a movement a body would be created which can speak with authority in allied matters of public health from all angles pertaining to the people of this State."

Number Nine is approved, but modified as follows That the President annually appoint a committee of five members of the State Society including himself and the Chairman of the Committee on Legislation with the approval and advice of the Council, and that the fact of such appointment be communicated to interested bodies such as the various state governmental officers and departments, and professional and lay organizations interested in medical and public health activities by the Secretary of the Medical Society of the State of New York."

Seconded and carried

Dr Kosmak Ten

#### ATTITUDE ON BILLS

"10 That the position of the State Society in relation to legislation as it may appear in the legislature be the same on such similar matters as has maintained in the past years unless a specific resolution be passed by the House of Delegates, by referendum vote or by the Council, thus changing the position of the Society without placing the burden of the change on the Committee on Legislation"

Seconded and carried.

Dr Kosmak Eleven.

#### STATE INSTITUTIONS

"11 That legislation which has come up in the past session in reference to the State Institute for the Study of Malignant Disease at Buffalo, and the State Hospital for Crippled and Deformed Children at West Haverstraw, be referred by the House of Delegates to the proper committee of the Society for study and suggestions as to action for your next Committee on Legislation The same report to be given to the Council by September 1st 1925, that they may act upon it for the guidance of the Committee on Legislation."

## ADJOURNED SESSION OF THE HOUSE OF DELEGATES, TUESDAY, MAY 12, 1925

The meeting was called to order by the Speaker at 9 30 a.m.

The Speaker We will hear the report of the Chairman of the Committee on Credentials

The Secretary The Committee on Credentials report that the roll is complete

The Speaker The Secretary will call the roll.

### ROLL CALL

The Secretary called the roll and the following delegates responded Nelson K. Fromm, L. Whittington Gorham, Thomas W. Jenkins, Chauncey R. Bowen, J. Lewis Amster, Edward R. Cunniffe, W. Meddaugh Dunnung, Cornelius J. Egan, Edward C. Podvin Norman Roth, Edmund E. Specht, Nathan B. Van Etten, Frank M. Dyer, Joseph J. Kane, William B. Johnston, Raymond C. Almy, Edgar Bieber, George W. Cotts, Reeve B. Howland, Leo F. Schiff, Charles D. Ver Nooy, John A. Card, James B. Sadlier, L. Franklin Anderson, Charles R. Borzilleri, W. Warren Britt Marshall Clinton, George R. Critchlow, James A. Gardner, Julius H. Potter, Sidney F. Blanchet, Sylvester C. Clemans, Clarence J. Whalen, Alton B. Daley, Charles J. Diss, Murray MacG. Gardner, John L. Bauer, William F. Campbell, Claude G. Crane, William H. Field, Charles H. Goodrich, Charles A. Gordon, Edwin A. Griffin, George D. Hamlin, Frank D. Jennings, John E. Jennings, William A. Jewett, Henry Joachim, J. Richard Kevin, William Linder, Walter D. Ludlum, Philip I. Nash, John J. A. O'Reilly, Harry H. Patrie, Charles E. Scofield, William Schroeder, Jr., James Steele, Alec N. Thompson, George H. Gage, Samuel H. Rosenthal, Willard H. Veeder, Floyd S. Winslow, Warren Wooden, David Wilson, Arthur D. Jaques, George A. Newton, Walter H. Conley, Edward C. Brenner, Milton A. Bridges, David E. Hoag, S. Dana Hubbard, Edward M. Cole, Jr., Daniel S. Dougherty, William M. Patterson, Harold Hays, William P. Healy, Ward B. Hoag, Samuel J. Kopetzky, George W. Kosmak, Samuel Lloyd, J. Milton Mabbott, Henry S. Patterson, James Pedersen, Otto H. Leber, Alfred C. Prentice, Abraham J. Rongy, Louis Tulipan, DeWitt Stetten, Terry M. Townsend, Luther M. Jayne, William A. Peart, Robert L. Bartlett, David H. Roberts, Andrew Sloan, Henry B. Doust, Frederick W. Sears, Homer J. Kuckerbocker, Warren B. Andrews, Frank E. Fox, Addison H. Bissell, Carl Boettiger, Thomas C. Chalmers, Henry C. Courten, L. Howard Moss, Joseph S. Thomas, Frank M. Sulzman, D. Vincent Catalano, E. Warren Presley, Charles D. Klune, Stanley W. Sayer, Carl R. Comstock, Dudley R. Kathan, Frederick C. Reed, LeRoy Becker, Allen W. Holmes, Robert M. Elliott, Herbert B. Smith, William J. Tracy, Frank Overton, William H. Ross, Luther C. Payne, Luther Emerick, Morris Maslon, Zenas V. D. Orton, Lucius H. Smith, Edward F. Briggs, Romeo Roberto, George B. Stanwix, Edward W. Weber, George B. Welker.

The following officers and chairmen of standing committees were present Owen E. Jones, George A. Leitner, Luzerne Coville, E. Eliot Harris, George M. Fisher, Andrew MacFarlane, James N. Vander Veer, Frederick H. Flaherty, Edward C. Rushmore, Frank H. Lasher, Arthur J. Bedell, Nelson O. Brooks, Harry R. Trick.

The following ex-presidents were present Arthur W. Booth, George H. Fox, Thomas H. Halsted, Grant C. Madill, Wendell C. Phillips, James T. Rooney, Charles Stover, Grover W. Wende.

### ELECTION OF OFFICERS

The Speaker There being a quorum present, the House is organized for business, and we will proceed to the election of officers. The first nomination is for President. The following officers were nominated and declared unanimously elected.

President, Dr. Nathan B. Van Etten, New York City, Vice-President, Dr. William H. Ross, Brentwood, Second Vice-President, Dr. Frederick H. Flaherty, Syracuse, Speaker, Dr. E. Eliot Harris, New York City, Vice-Speaker, Dr. George M. Fisher, Utica, Secretary, Dr. Daniel S. Dougherty, New York City, Assistant Secretary, Dr. Howard G. Myers, New York City, Treasurer, Dr. Charles Gordon Heyd, New York City, Assistant Treasurer, Dr. James Pedersen, New York City, Chairman of the Committee on Scientific Work, Dr. Andrew MacFarlane, Albany, Chairman of Committee on Public Health and Medical Education, Dr. Charles A. Gordon, Brooklyn, Chairman of Committee on Medical Economics, Dr. William W. Britt, Tonawanda. Upon motion duly seconded and carried the selection of the Chairman of the Committee on Legislation was left to the Council. Upon motion, duly seconded and carried, the selection of the Chairman of the Committee on Arrangements was left to the Council. Committee on Prize Essays, Dr. Lucien Howe, Buffalo, Dr. John E. Jennings, Brooklyn, Dr. Thomas H. Curtin, New York City, Censors. To consist of the President and Secretary and eight District Councillors, as provided by the Constitution.

Five delegates to the American Medical Association, for two years: Dr. Owen E. Jones, Rochester, Dr. Arthur W. Booth, Elmira, Dr. Grover W. Wende, Buffalo, Dr. Grant C. Madill, Ogdensburg, and Dr. William Francis Campbell, Brooklyn.

Five alternates to the American Medical Association for two years: Dr. James N. Vander Veer, Albany, Dr. George A. Leitner, Piermont, Dr. Nelson O. Brooks, Oneida, Dr. L. Howard Moss, Richmond Hill, and Dr. Edward C. Podvin, New York City.

The Speaker We will hear reports of the Reference Committees.

### SECRETARY'S AND TREASURER'S REPORTS

Dr. Pedersen, Chairman of the Reference Committee on the Report of Secretary and the Report of the Treasurer. We have the honor to submit the following recommendations:

As to the Secretary's report: Your Committee recommends that the plan to conserve the Society finances, as outlined in the report, be endorsed without, however, necessarily establishing a so-called "sinking fund" now. The Committee feels that the subject of a sinking fund should be postponed for discussion a year or more.

In consequence of the increased dues, your Committee anticipates a considerable balance at the close of the current year. Therefore, we recommend that a conservative budget be submitted by the Executive as provided by the By-laws, and that the major part of any balance remaining at the close of the year be temporarily invested under the control of the Council.

As to the Treasurer's report: It having been audited and found correct, your Committee recommends its acceptance.

Seconded and carried.

Dr. John E. Jennings, Reference Committee on the Report of Council and Councillors.

### REPORTS OF COUNCIL AND COUNCILLORS

The Committee recommends the acceptance of the report of the Council but calls attention to the neglect of Council to comply with the spirit of the recommendation of the House of Delegates in adopting the report and recommendation of the Reference Committee C at the annual meeting of the House of Delegates held in Rochester in 1924, namely, that such amendments to the Public Health Law as are necessary be formulated by the Council and by them referred for approval by referendum sent by mail to the House of Delegates.

The action of the Council on February 18, 1925, approving measures already before the Legislature and ordering a referendum of the House of Delegates, on

mit them to the Council by the 1st of December, 1925, should the Council pass favorably upon their introduction

Recommendation Sixteen is approved by the Committee.

Seconded.

Dr O'Reilly A point of information Is it recommended that the committee in charge of this matter be continued, or a similar committee be appointed?

The Speaker That is left to the President to make a choice either way All in favor of that motion say Aye, opposed, no Carried

Dr Kosmak Seventeen

#### LEGISLATIVE SUGGESTIONS

"17 That any legislative suggestion or thought within or by a County Society shall be in the hands of the Council for approval or disapproval not later than September 1st, 1925"

Your committee approves that recommendation

Dr O'Reilly A point of information, isn't that the same proposition as number eight?

The Speaker The recommendation number eight was carried Number seventeen is the same as number eight and no action is necessary

Dr Kosmak Eighteen

#### DIRECTING EXECUTIVE OFFICER

"18. That the House of Delegates direct that the services of the Executive Officer shall be wholly under the direction of the Committee on Legislation from the 1st day of December until one month after the closing of the legislative session"

Dr MacFarlane I move as an amendment to that paragraph "The House of Delegates directs that the services of the Executive Officer shall be largely under the direction of the Committee on Legislation," not entirely so

Seconded

Dr Phillips I move that eighteen be referred to the Council, with power

Seconded, and, upon a rising vote, carried

Dr Kosmak Nineteen

#### PRESS BUREAU

"19 That some means be devised whereby articles on medical topics may be syndicated to newspapers through the editorial office of the Journal, or a Press Bureau to be established within one of the standing committees of the Society, from whence can be sent to newspapers, lay organizations, churches, schools, and the like, authentic and interesting articles concerning the public health and the duty of the individual in relation to the health of his neighbor This is one of the crying needs of the Society at the present time and it might be of advantage to the Society were some journalist engaged upon half or full time to help the committee upon whom such work would fall

Your Committee approves this recommendation and requests that it be referred to the Council for further action

Seconded and carried.

Dr Kosmak I move that the report as amended be adopted as a whole Seconded

#### ACTION ON THE REPORT AS A WHOLE

Dr Frank Jennings Action on question 12, as I understand it, was a blanket action on the basis that in having passed number 10 we passed 12 Is that right? I voted in the affirmative on number 10 I would like to move for the reconsideration of number 10

Seconded

Motion to reconsider the adoption of number 10 is lost.

Dr Ludlum, Brooklyn As I understand it, section 12 was passed by unanimous consent by declaration of the Speaker That is my understanding Therefore, we can proceed to the reconsideration of number 12, if

we so desire, and I therefore, subject to correction, as to Parliamentary procedure, move that we reconsider number 12, which we unanimously passed by consent.

The Speaker Your motion to reconsider is in order

Dr Ludlum I so move.

Seconded

Motion to reconsider the adoption of number 12 is lost.

Dr Ludlum We have not been enlightened as to our exact position on this situation I suppose we are opposed to Birth Control, anti-vivisection, and Child Experimentation by the action so far taken, but can take action when other reports of this committee are brought in Is that where we stand? The House of Delegates stands opposed to these first three and in favor of the Karle-Dunmore bill?

Dr Kosmak I think it was the idea that we would endorse the recommendation of the Chairman of the Committee on Legislation in reference to the changes made by these measures by any other means than those which are referred to, that is to say by the House of Delegates or by referendum vote, or by the Council changing the position of the Society and not placing the burden of such changes on the shoulders of the Chairmen of the Legislative Committee.

In recommendation 12, the action of the House of Delegates on these three bills is acknowledged, I believe The action on the question of the amendments to the Medical Practice Act I believe has been concluded by the referendum made by the Society, and therefore we accepted that interpretation Now the action of the Society was against these other three bills and it was in favor of amendments to the Medical Practice Act

Dr Ludlum I still do not think we are taking proper action on 12 The recommendation is that this House of Delegates discuss The Speaker of the House declared that this matter had been disposed of by number 10 How a discussion can be disposed of in that way is hard to understand, that is the discussion was closed by not being entered into

Dr O'Reilly A point of information I cannot vote upon this in view of the statement of the Speaker that number 10 covers number 12, and that number 12 required no vote We are now voting upon this report as a whole, making number 10 inclusive of number 12

Dr Ludlum Is it now in order to appeal from the decision of the Speaker, made an hour ago, that 12 was covered by 10?

The Speaker An appeal from the decision of the chair must be made before any debate or new business intervenes The announcement of a vote is not a decision of the Chair, therefore not subject to appeal The speaker's decision was that the House of Delegates unanimously carried the adoption of No. 12 as recommended by the Reference Committee. Then separate motions were made to reconsider No. 10 and No. 12 and both motions to reconsider were lost The only way you can further reconsider No. 10 and No. 12 is by unanimous consent.

Dr Kosmak Moved the adoption of the report as a whole.

Seconded and carried

#### MEDICAL PRACTICE BILL (see page 803)

Dr Kosmak With reference to the resolutions introduced by Dr Chalmers, of Queens, we desire to express our disapproval, as these are contrary to a referendum vote taken during the Legislative session of 1925

Seconded

The Speaker It is moved and seconded that the recommendation of the Committee be adopted

Are you ready for the question? All in favor of adopting the report of the Committee will signify by saying aye. Opposed, no The Chair is in doubt.

Upon a rising vote the motion was carried.

Upon motion, duly seconded, the meeting adjourned to Tuesday morning, May 12, at 9 30 in the forenoon

cal education The Reference Committee recommends that the promotion of graduate medical education be one of the major activities of the State Medical Society during the coming year The need and the desire for graduate medical education exists and it only awaits practical organization of method There is abundant evidence of the truth of this statement in the result of efforts made in several States and Counties, notably Kings

In these times of rapid change of knowledge and practice there is need for some method of providing a steady stream of medical information to all sections away from medical centers as well as to make available to city practitioners the results of medical progress This work belongs to organized medicine.

Keeping every physician in the State fully informed as to advancing medical knowledge would be the most potent factor in the advancement of public health The Reference Committee recommends that the House of Delegates authorize the Council to request the House of Delegates of the American Medical Association to cooperate with the Medical Society of the State of New York to the end that all available material for graduate medical instruction including teachers, charts, lantern slides, moving pictures, etc, be made available to the appropriate committee of the Medical Society of the State of New York for carrying out this plan and that the Council be authorized to appropriate as much money as it may deem expedient for the work of graduate medical instruction

I move its adoption

Seconded and carried

Dr Wightman I would like to introduce two amendments.

#### AMENDMENTS TO CONSTITUTION

Amend section 20 of the By-laws, second line, by striking out the word "Society," and inserting the words "House of Delegates"

Amend section 28 by striking out on line 2, the words, after the word Council," and before the word 'shall,' on the third line.

The Speaker They will be placed on file.

#### WHEN TERM OF DELEGATES BEGIN

Dr Wightman Another matter I would like to bring to your attention is relative to the election of delegates, and I would like to offer this as a resolution The term of a delegate elected by a component county medical society shall begin at the first annual meeting of the House of Delegates subsequent to his election.

Dr Kevin I move you as a substitute to the motion, that Dr Wightman be appointed a committee of one to make recommendations for the solution of this question to the next House of Delegates

Seconded and carried.

The Speaker Dr Wightman is so delegated

The Speaker We will hear from the Chairman of the Reference Committee on Medical Economics

#### COMMITTEE ON MEDICAL ECONOMICS

Dr Britt Your Reference Committee on Medical Economics begs to report as follows Owing to the illness of Dr Henry Lyle Winter, his report was not received in time for publication in the printed reports Your Reference Committee wishes to commend Dr

Winter for the careful and extensive report submitted and recommend that this House of Delegates extend to Dr Winter a vote of thanks for his faithful service to this Society during his long term of office

Seconded and carried

Dr Britt We would like to submit the report of Dr Winter and read it to the House of Delegates

Dr Chalmers I move the report be printed in the next issue of the Journal

Seconded

Dr Mabbott May I ask the Chairman whether there is anything important in it, in his opinion, which ought to be read to us now, and whether he could select any small portion of it that is important

Dr Britt It is submitted under the following headings

- 1 The Work of the New York State Council of Rural Workers
- 2 Nursing Problems
- 3 Health Insurance.
- 4 Workmen's Compensation
- 5 The Medical Practice Act.
- 6 Health Centers, with special reference to the plan adopted by the Medical Society of the State of California.
- 7 Pay Clinics

During the current year the increased activities of the advocates of Birth Control have attracted notice and your Committee has had the subject under consideration

Dr Ludlum It seems to be impossible to consider an attractive report like this without having the opportunity to consider it in advance Therefore, I would move that this report be referred to the Council with power

Seconded and carried

The Speaker Has any member introduced a resolution that has not been reported back by a Reference Committee?

The Vice-Speaker took the chair

#### VOTE OF THANKS TO COMMITTEE ON ARRANGEMENTS

Dr Bedell I move you, sir, that this House go on record as thanking the local arrangements committee for the entertainment that they have provided for us, and that that expression be transmitted to Dr Flaherty as Chairman of the Committee.

Seconded and unanimously carried by a rising vote

#### COMMITTEE TO DRAFT MEDICAL PRACTICE ACT (see page 803)

Dr Chalmers In order that we may all get together and have a Medical Practice Act next year which we can all support, I wish to offer the motion, that the President shall appoint a Committee of seven with power to draft a Medical Practice Act which shall be the official bill of this Society, and that the same be published in the September issue of the Journal.

Seconded

Upon motion, duly seconded and carried, the rule that all resolutions go to a Reference Committee was suspended, whereupon the motion of Dr Chalmers was carried

Upon motion, duly seconded and carried, the meeting adjourned.

E. ELIOT HARRIS *Speaker,*  
EDWARD LIVINGSTON HUNT, *Secretary*

its approval is not deemed a full compliance with the recommendations of the House of Delegates

The Committee recommends the adoption of the reports of the Councillors of the third, fifth, sixth, seventh and eighth district branches, but calls attention to the neglect of the Councillors of the first, second and fourth district branches to submit reports

I move its adoption

Seconded

The Speaker The legal counsel was requested to answer the question in regard to the implied censure of the Council

Mr Whiteside What are the questions?

Dr Kopetzky I ask, through the Speaker, that the Counsel of the Society inform us of any neglect of the Council to carry out the mandate of the House of Delegates, so that I may vote intelligently

Mr Whiteside The inquiry is directed toward the making of a defense against a charge of neglect, apparently. It appears there is a charge of certain neglect against the Council. Before entering into a discussion of the merits, as to whether or not there was any neglect, I would like to consider whether the Council should be placed in a position where it even ought to discuss the question. The Council of the Society is the executive department of the Society, clothed with all executive powers. It occupies the same position in the government of this Society that the executive of the State occupies in the government of the State. This House of Delegates is a legislative branch of the Medical Society of the State of New York. The Council is its executive branch. They are independent one of the other, except as far as the power of the House of Delegates reaches out to legislate upon matters concerning the affairs of the Society.

It is no function, if I may say so, of the House of Delegates to pass votes of censure upon any executive officer, and for the same reason it is my opinion that the House of Delegates has no power to criticize any executive officer. They may have a right under the By-laws or the Constitution to file charges against any officer, or any particular body in the Society, and to try those charges on the merits, sitting as a court to hear the evidence and to determine the facts thereon, but simply in the form of a resolution or in the form of a report, I am of the opinion that this House has no power to pass judgment in the nature of criticism, or to make a charge of this character, either directly or by innuendo, reflecting upon Council of the Society.

If the first point is well taken, it may be unnecessary to proceed to the second, which would be a discussion of the merits.

May I ask what is the decision of the House on this point?

Dr Kopetzky I arise to make a point of order since the gentleman has not the right to do so. I make the point of order that under the argument as presented by counsel, the consideration of a report carrying an implied criticism of an executive of this Society is out of order, and that the consideration of that portion of the report is therefore out of order.

The Speaker As the Speaker happens to be a member of the Council, modesty forbids his deciding the point of order and therefore he submits it to the House. All in favor of that portion of the report reflecting upon the Council shall be stricken out as out of order say aye opposed no.

Motion carried

The Speaker The House has stricken that out of your report Dr Jennings the censure of the Council. Upon motion, duly seconded, the report as deleted, was adopted.

#### COMMITTEE ON NURSES

Dr Andrew Sloan Chairman of Committee on Report of the Special Committee on Nurses

"The Committee on Report of the Special Committee on Nurses has carefully analyzed the printed report of

the Committee on the nurse problem and has reviewed various opinions and records, verbal and written offered by members of the House of Delegates and others.

The Committee recognizes the value of many of the suggestions, has not included any suggested legislative changes, and believes that the subject is so tremendous that no final decision regarding supply and demand, training, legislation, or other attempts at solution should be outlined or devised without careful consideration in conference between the medical and nursing professions.

This Committee approves the report of the Committee on nurse problem as printed and their recommendations.

(a) That a Nurse Committee be appointed by the President to work in conjunction with the Committee on Medical Economics to study the problems of the nurse and report annually or oftener to the Society.

(b) That the same committee be authorized to confer with the State Education Department on matters concerning Nurse Education, and especially on that which concerns the proper balance of theoretical and practical training and instruction.

We feel that the Committee on the Nurse Problem has given the subject very careful and thorough study and has earned the thanks of the House of Delegates.

I move the adoption of Section A

Seconded

Dr Dougherty A point of information. It says to report annually or oftener to the society. That means that the Committee might on an inconsequential matter call a special meeting of the Society.

Dr Sloan It was the understanding of the Committee that they report back to the representative of the House of Delegates, which would be the Council.

The Speaker Make that change.

Upon motion, duly seconded, recommendation A was adopted as amended.

Dr Sloan I move the adoption of section B

Seconded and carried

Dr Sloan I move the adoption of this report as a whole.

Seconded

Dr Critchlow I move an amendment to the motion to adopt this report as a whole, the last portion of the report has been adopted. A and B are the recommendations of this Committee. I move that the Committee's report as a whole be received and filed.

Seconded

The Speaker When a report is read it has been received. It is moved that the report as a whole be filed.

Dr Kopetzky I wish to move to amend the motion that is pending, namely the adoption of the Reference Committee's report as a whole and amend it to read "The Reference Committee's Report be adopted as a whole, with this amendment, that in adopting, due and special consideration be given to the facts as presented to this House of Delegates by Erie County."

Seconded and carried

The Speaker Now you will vote on the adoption of the report as a whole with the amendment added as voted. All in favor say aye. Opposed no. Carried.

#### COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION (see page 808)

Dr Ross Report of Reference Committee on Public Health and Medical Education

"The Report of the Committee on Public Health and Medical Education consists of suggestions for ten activities which might be considered by the State Medical Society. The Reference Committee endorses all of these suggestions, but especially emphasizes two of the subjects touched upon in the report. Suggestions one and ten relate to periodic health examinations. Your Committee endorses the movement and recommends that it be promoted in the pages of the JOURNAL and by county societies."

Suggestions four six and seven relate to graduate medi-

## IN PROSPECT

Every spring the Medical Society of the State of New York lightly turns to new leadership, thus following time honored tradition, wisely obtained no doubt, but often thrusting serious responsibilities upon untrained and inexperienced men who must inevitably waste valuable time in acquiring understanding of fundamentals.

In giving a courtesy seat at the council table to the Editor of the JOURNAL, my predecessor, Dr Jones, offered the opportunities for observation that he recommends for the man who next year, if the House of Delegates passes the constitutional amendment, shall be the President-elect. Overlapping trusteeships will also help to maintain continuity of knowledge and simplify administration of finances. The American Medical Association here wisely shows us a working model and further carries out the spirit of continuity of service in electing to the Presidency Dr Wendell C Phillips, whose long experience as trustee and as a student of organized medicine has developed an officer without a peer in this country. The Medical Society of the State of New York will undoubtedly continue to enjoy his active service and his wise counsel.

The council is a new one, very largely, but represents enthusiasm based on experience which will surely be valuable to the Society and will stimulate active interest.

We are warranted in expecting developments from a very active Committee on Economics working with several sub-committees, one studying very seriously the nurse question, which seems to be chiefly an economic problem in which the law of supply plays a leading rôle. Active committees are studying workmen's compensation laws and other economic problems, and a general committee will try to discover the needs of our members through consultation with the chairmen of local county committees which are engaged upon related economic questions.

The conference of County Society Secretaries with Presidents of District Branches promises valuable returns from serious discussions of local problems which may be sample problems with solutions applicable to every County Society.

The development of a new medical practice act or a new plan for constructive legislation from a special committee under the chairmanship of Dr John E Jennings of Kings, awakens renewed interest in questions which have led to serious local disagreements, and to renewed hope that unanimous support will be given to whatever legislative program may be decided upon by referendum of the House of Delegates.

The House annually elects officers, passes resolutions and recommendations to them and then awaits, usually very calmly, its annual dissolution. The Members of the House of Delegates should remember that they are themselves officers of the Society until the moment that the Speaker forms the new House at the

next annual meeting. They should be actively interested in their own legislation, and should communicate their individual opinions with great freedom to their elected representatives and so develop a body of opinion which would unquestionably be respected.

With the support of a Governor who is eager for constructive legislation favoring any valuable public health program, organized medicine should present a united front at the next legislative session. The past history of our State reveals no other Governor with such ideals and the future may be equally barren.

The Committee on Scientific work is already at work upon the program for the next annual meeting and basing their efforts upon their recent successful experience, have reason to hope for a meeting which will attract a very large attendance. The chairman of this standing committee is the only chairman carrying on from last year and is fortunate in having acquired a momentum which will carry him over many difficulties.

From the new program of post graduate medical education now being developed by the new chairman of the Committee on Public Health and Medical Education, we expect that most active interest will be excited among our members. Every busy doctor knows that he has limitations, every busy doctor desires with all his heart to keep up to date with the practical as well as the scientific side of medical progress. The active doctor is too busy to stop his daily work and go to school again, as in fact he should, for a few weeks every year. This new committee proposes to evolve a plan to carry this practical material to the doctor in his own county at conveniently located places, and from experience already gained from a completed experiment, feels sure that the State Society will exhibit an accomplishment that will stimulate other state societies to attempt similarly ambitious programs.

The group insurance opportunity now embraced by half of our members deserves our full support. As has often been said, it is incomprehensible that any doctor, no matter how limited his field, should have the temerity to practice his art one moment longer without ample protection. The fact that our legal counsel is regarded as the most eminent specialist in defense of whom we have knowledge, does not justify us in recklessly puffing out our chest so that the blackmailer may have a better target.

An improved JOURNAL is assured by the promise of a stronger editorial staff, by new business methods, and by a growing general interest in a most valuable organ. The next Directory will be strengthened by the addition of the list of the Hospitals of the State and of the Physicians who serve them.

The prospect is a busy one and should arouse a lively enthusiasm.

## DR WENDELL C PHILLIPS, PRESIDENT-ELECT OF THE AMERICAN MEDICAL ASSOCIATION

It is with pleasure that we offer our congratulations to a fellow member and ex-president of our State organization, Dr Wendell C Phillips, who was unanimously elected president-elect of the American Medical Association, the highest medical body, and probably the most influential medical organization in the world.

Dr Phillips is peculiarly fitted to fill this high office. He has given years of unselfish devotion to the ideals and upbuilding of medical progress in the United States. No one ever will be able to compute the time, the thought and the effort which Dr Phillips has given toward promoting the interests of the medical profession. He combines personal charm and tact, together with a dignified bearing, which makes him a most ac-

ceptable presiding officer at any gathering, his tireless effort and patience, and his willingness to adopt anything which promises improvement, have fitted him particularly well to guide the affairs of the American Medical Association. The delegates of New York State are glad to say that they were not only unanimous in his support as a candidate for this office, but that they will likewise be unanimous in helping him in every way to make his administration a great success. New York has been honored in the selection of Dr Phillips and we believe that he will have the unqualified support, so well deserved, of everyone throughout the union who has the welfare of the medical profession at heart.

# NEWS NOTES

## AMERICAN MEDICAL ASSOCIATION CONVENTION OF 1925

Attending the national convention of the American Medical Association in the capacity of a delegate offers many opportunities for careful study of the live issues at present before the profession

1925 has been a year of progress in medicine throughout the United States

After the convention was well under way, various committees previously appointed made their reports And, inasmuch as these reports contain the essence of progress during the year, a brief summary will be attempted

The committee from the Board of Trustees, in speaking of the A M A JOURNAL, stated that during the year 4,410,220 copies had been printed, which was an increase of more than 176,000 over the previous 12 months During this period the JOURNAL had received from advertisement \$614,084 00, an amount slightly less than the year previous It was interesting to learn that the Spanish edition showed a deficit of \$12,902 00 which had fortunately been met by the Rockefeller Foundation

Another publication of the A M A which showed healthy signs of growth was *Hygeia*, whose circulation had risen from nineteen to thirty-two thousand It was an interesting fact that in spite of this increase the magazine was still running at a loss—that of the past year being \$42,745 00 In other words, any magazine to be self-sustaining must require a definite interval in which to "find itself" *Hygeia*, however, gives every sign of vigorous growth and within the next few years should be self-supporting

The Committee on Full-Time Officers, through Dr Cramp, stated that the Bureau of Information in Chicago was doing very efficient work They spent a great deal of time in replying to questions from physicians as well as lay societies, giving the necessary information asked for They stated that it would be highly desirable if everybody knew the amount of information in the possession of this Bureau and they were at the service of the medical profession throughout the country In speaking of the investigation of the Abrams Fake, it was pointed out that in 1922 and 1923 this pseudo-method of treatment was on the down grade and that in 1924 it had practically passed They wished to correct the impression that the medical men of Great Britain looked with favor upon Abrams and his methods Considerable newspaper notoriety had been given to this matter—all of which was absolutely untrue.

Dr Woodward, who was the Secretary of Legal Medicine and Legislation, was very glad to state that he had had the full cooperation of the various states in the Union during the past year His efforts had been particularly with the Department of Internal Revenue relative to improving the Narcotic Bill and making it less onerous for physicians He stated that the chiropractors of the Veterans' Bureau numbered six at the present time in training, that there would be no new ones after the 30th of June and all of this ill-advised training would be completed by 1926

In the matter of mal-practice suits the Bureau is not yet willing to make any recommendations Fifteen states had spent \$36,663 00 for medical defense covering 43,000 physicians There had been a marked increase in the number of mal-practice suits against doctors This has been so often emphasized by our own State Counsel, Mr George W Whiteside, that it needs but little comment At no distant date the absolute protection of the physician will require that every doctor be insured through properly incorporated insurance companies, and this task of mal-practice defense will not be the work of any State Society In the old days when the claim for damages was small and recoveries were infrequent, mal-practice suits had not attained proportions they have reached at the present time The whole question is in a state of development The public have unfortunately been taught that large judgments can be secured from physicians and hence old methods are no longer applicable to present needs

The Bureau at Chicago is constantly fighting to secure the repeal of the Federal narcotic tax on physicians of \$3 00 so that the medical fraternity may be spared this injustice It never has been the amount involved, but rather the principle This question, however, is so big that it cannot be solved in a short time

Under Health and Public Instruction, Dr Dodson again emphasized the wonderful work *Hygeia* was doing, drawing attention to the fact that they had a clipping bureau in connection with this magazine which could be used to advantage by many other Journals It might be well for these interested in these terse comments to get in touch with Dr Dodson's Bureau The Department had a Speakers' Hand-book for publicity work in press They had found it advisable in medical matters to use the radio, two stations being used in Chicago and eight in other cities throughout the country He stated that

## THE TUBERCULOSIS SESSION

The last day of the meeting of the State Society has always been a bugbear and nightmare to the Committee on Scientific Work. There is always so much semblance to a funeral, without the joy of a wake, that each year it has been seriously considered whether or not these last day sessions should be discontinued or the agony prolonged for another year.

At this year's meeting an innovation was put into effect. Instead of the presentation of papers it was decided to give over the entire day to the complete consideration of one single disease in all its protean and diffuse manifestations.

Tuberculosis was selected as the disease which would naturally appeal to every physician, no matter what his intensive or extensive field of medical work might be.

The underlying feeling was that the presentation of a disease from every aspect not only demonstrated the unity of disease but also was a demonstration of the entire field of medicine. Osler wisely stated—know syphilis and all disease is known. Know tuberculosis and all disease is an open book, is equally true.

The unexpected and great success of this last day's meeting with almost 200 new registrants and about 600 visitors reveals a new and helpful phase of work for future meetings. The complete presentation in a similar way of syphilis and cancer during a whole day's session would be such an attractive program that it would draw hundreds and even thousands of physicians who never attend or take interest in the meeting of the State Society. The sessions, instead of being wasted, as in previous years when ten to fifteen tired physicians, constantly consulted time tables and then watches, were crowded with 600 alert visitors who were keenly anxious to absorb

everything which might be helpful in their battle against this ever present disease. The morning session consisted of a demonstration of pathological and bacteriological specimens of human and bovine tuberculosis, exhibition of X-ray findings in infancy, childhood and adult life, together with the interpretation and significance of chest radiograms. Probably the most popular section was the presentation of the moving pictures of pulmonary tuberculosis and demonstration charts by Dr. L. Gregory Cole of New York City. Physical signs were demonstrated by the stethophone and the value of heliotherapy and the mercury lamp illustrated by the presence of a group of lively, happy youngsters who were clothed only in loin cloths and continuous smiles, a possible prophecy of the flapper of the future.

The morning session was closed by short, practical, illustrated talks by specialists which held a vast audience until the last word was spoken.

The afternoon session was given over to concise, snappy addresses without discussion, by authorities in the field of tuberculosis. That these addresses were thoroughly appreciated is evidenced by the fact that the auditorium was overcrowded up to the last word. It would take an entire number of the JOURNAL to properly describe these sessions. There was a feeling of intentness and tenseness in the air which made everyone feel that they were taking part in the most complete demonstration of this subject ever presented.

Every physician present felt abundantly repaid for remaining an additional day, while those who were unable to be present missed an opportunity of having solved for them the many problems of tuberculosis.

ANDREW MACFARLANE.

## INTEREST IN MEETINGS OF COUNTY MEDICAL SOCIETIES

We have frequently heard discussions on the subject of how to make the meetings of county medical societies interesting and attractive, and how to increase their attendance. Suggestions have been made that meetings be held more frequently and that more committees be appointed. We have sought for a practical scheme which will apply to every county society—one which will require little machinery, and which has been demonstrated to work.

The plan which we suggest is that of clinical programs for the meetings.

How will a clinical program be carried out? In the first place a teacher will be needed. The State Society is now providing the means by which one will be available for any group anywhere in the State.

In the second place, the members of the society

or group will provide six patients for study and diagnosis. The object is to teach the doctors, although of course the patients will get the benefit of free advice.

What is likely to be the course of events in a society in which one clinical program is introduced? Where the experiment has been tried and the members attend one clinical meeting, they ask for another to be held within a month, then the next step is a series of teaching clinics, or a system of graduate education in that county, and by that time the problem of interest in the meetings of the society is solved.

We offer this plan for increasing the interest in county societies as the most natural and most practical one which we have heard suggested.

F. O.

Suggestions have been made that meetings be held more frequently and that more committees be appointed. We have sought for a practical scheme which will apply to every county society—one which will require little machinery, and which has been demonstrated to work.

The plan which we suggest is that of clinical programs for the meetings.

How will a clinical program be carried out? In the first place a teacher will be needed. The State Society is now providing the means by which one will be available for any group anywhere in the State.

In the second place, the members of the society

or group will provide six patients for study and diagnosis. The object is to teach the doctors, although of course the patients will get the benefit of free advice.

What is likely to be the course of events in a society in which one clinical program is introduced? Where the experiment has been tried and the members attend one clinical meeting, they ask for another to be held within a month, then the next step is a series of teaching clinics, or a system of graduate education in that county, and by that time the problem of interest in the meetings of the society is solved.

We offer this plan for increasing the interest in county societies as the most natural and most practical one which we have heard suggested.

F O

# NEWS NOTES

## AMERICAN MEDICAL ASSOCIATION CONVENTION OF 1925

Attending the national convention of the American Medical Association in the capacity of a delegate offers many opportunities for careful study of the live issues at present before the profession.

1925 has been a year of progress in medicine throughout the United States

After the convention was well under way, various committees previously appointed made their reports. And, inasmuch as these reports contain the essence of progress during the year, a brief summary will be attempted

The committee from the Board of Trustees, in speaking of the A M A JOURNAL, stated that during the year 4,410,220 copies had been printed, which was an increase of more than 176,000 over the previous 12 months. During this period the JOURNAL had received from advertisement \$614,084 00, an amount slightly less than the year previous. It was interesting to learn that the Spanish edition showed a deficit of \$12,902 00 which had fortunately been met by the Rockefeller Foundation

Another publication of the A M A which showed healthy signs of growth was *Hygeia*, whose circulation had risen from nineteen to thirty-two thousand. It was an interesting fact that in spite of this increase the magazine was still running at a loss—that of the past year being \$42,745 00. In other words, any magazine to be self-sustaining must require a definite interval in which to “find itself.” *Hygeia*, however, gives every sign of vigorous growth and within the next few years should be self-supporting

The Committee on Full-Time Officers, through Dr Cramp, stated that the Bureau of Information in Chicago was doing very efficient work. They spent a great deal of time in replying to questions from physicians as well as lay societies, giving the necessary information asked for. They stated that it would be highly desirable if everybody knew the amount of information in the possession of this Bureau and they were at the service of the medical profession throughout the country. In speaking of the investigation of the Abrams Fake, it was pointed out that in 1922 and 1923 this pseudo-method of treatment was on the down grade and that in 1924 it had practically passed. They wished to correct the impression that the medical men of Great Britain looked with favor upon Abrams and his methods. Considerable newspaper notoriety had been given to this matter—all of which was absolutely untrue

Dr Woodward, who was the Secretary of Legal Medicine and Legislation, was very glad to state that he had had the full cooperation of the various states in the Union during the past year. His efforts had been particularly with the Department of Internal Revenue relative to improving the Narcotic Bill and making it less onerous for physicians. He stated that the chiropractors of the Veterans' Bureau numbered six at the present time in training, that there would be no new ones after the 30th of June and all of this ill-advised training would be completed by 1926

In the matter of mal-practice suits the Bureau is not yet willing to make any recommendations. Fifteen states had spent \$36,663 00 for medical defense covering 43,000 physicians. There had been a marked increase in the number of mal-practice suits against doctors. This has been so often emphasized by our own State Counsel, Mr George W Whiteside, that it needs but little comment. At no distant date the absolute protection of the physician will require that every doctor be insured through properly incorporated insurance companies, and this task of mal-practice defense will not be the work of any State Society. In the old days when the claim for damages was small and recoveries were infrequent, mal-practice suits had not attained proportions they have reached at the present time. The whole question is in a state of development. The public have unfortunately been taught that large judgments can be secured from physicians and hence old methods are no longer applicable to present needs

The Bureau at Chicago is constantly fighting to secure the repeal of the Federal narcotic tax on physicians of \$3 00 so that the medical fraternity may be spared this injustice. It never has been the amount involved, but rather the principle. This question, however, is so big that it cannot be solved in a short time

Under Health and Public Instruction, Dr Hodson again emphasized the wonderful work *Hygeia* was doing, drawing attention to the fact that they had a clipping bureau in connection with this magazine which could be used to advantage by many other Journals. It might be well for these interested in these terse comments to get in touch with Dr Dodson's Bureau. The Department had a Speakers' Hand-book for publicity work in press. They had found it advisable in medical matters to use the radio, two stations being used in Chicago and eight in other cities throughout the country. He stated that

1200 newspapers were using the clipping service of *Hygeia*, covering a circulation of twenty-two million people. He wanted to impress upon the delegates the fact that a great change was coming over the community relative to health education. They were beginning to believe that health comes first and was most important, and that the movement for periodical health examination was growing and he was glad to state that their Manual on this subject should be out within a few weeks.

The meeting was most fortunate in having as its guest Mr. Hall, who is President of the British Medical Association. Mr. Hall stated some of the difficulties of his particular task at home. He dwelt especially upon health insurance and stated that under the Lloyd George administration the physicians of Great Britain were poorly organized, that Mr. George made them a proposition relative to health insurance examinations, fixing the amount that the state would pay. He further stated that unless the physicians as a whole would accede to this demand, he had already secured consent from a sufficient number of physicians to carry out the plan. Mr. Hall stated that recently when the Government made up its mind to diminish the fees allowed physicians, various civic bodies arbitrarily suggested to the government a very low rate for this service. This was considerably below what the medical fraternity felt they could work for. As the controversy developed, a referendum was sent to the medical fraternity, which was now thoroughly organized, and 96 per cent responded refusing to work under the terms offered by the civic body. This brought about a very prompt reconsideration of the subject with the result that the doctors' demand was promptly met. Mr. Hall pointed out the need of unity in medical action—not as a union in the trade sense of the word—but in the sameness of ideals so as to bring about fairness and justice to all. He said that anything could be accomplished by the medical profession if they stood united. Coming from a foreigner after our own varied experience, this was most assuredly helpful.

Dr. Haggard, the new President of the American Medical Association, briefly outlined the duties of the hour. He thought that our present medical education was somewhat too technical. The time for developing a physician should be shorter. One suggestion was that instead of long summer vacations there should be four sessions so as to carry out a completed year. He felt that where such institutions issued diplomas to their graduates, and this particularly applied

to State Institutions, this in itself should be a sufficient preliminary for the various medical examining boards of the State. Dr. Haggard felt the need of a minimum education requirement in all medical matters. He felt that there should be a fundamental training in preparation and that after that people could use any particular method of practice they wished.

Relative to legislation, the sentiment of the physicians seemed to be that professional lobbying on the part of the Medical Fraternity was a bad thing, that the way to affect law making bodies was to go to the representatives before election and before they had gone to the various legislative chambers, to personally express the opinions of the medical profession and not to join the professional lobbying class. Dr. Haggard likewise stated that he hoped to make Periodical Health Examinations the keynote of his administration, and that in the very near future he would call a conference of those who had already done this work so as to secure the best information which might be of help in perfecting a policy applicable to the various states in the Union.

Things which will interest the profession at large were the creation of a Section on Radiology and the omission of the Section on Stomatology. It was also voted to increase the House of Delegates from 150 to 175, and reapportion the representatives on a basis of 1 to 750 members.

The nursing problem was in a condition of flux, the convention recognized the transformation which was taking place, and a committee was appointed to study this whole matter and report at the next meeting.

The recommendation relative to the unrestricted prescribing of alcohol by physicians was unanimously carried. This is no wise involved the legal observation of the Volstead amendment and had no bearing upon alcohol other than in a medical sense.

On the whole the meeting was most successful. One could not attend such a gathering without being impressed with the seriousness of medical thought in America. Mr. Hall, whom we have already quoted, stated it was a great pleasure to come to America and secure so great an inspiration. He had no idea that our activities were so intense and varied, and he felt that his coming would enable him to carry back to the British Isles much that was worth while. It was voted to hold the 1926 meeting of the American Medical Association in Dallas, Texas.

O S W

## AMERICAN MEDICAL ASSOCIATION

We are highly pleased with the meeting of the American Medical Association, which was held in Atlantic City, New Jersey, during five days beginning Monday, May twenty-fifth. We went for the specific purpose of observing the many features of the meeting as we happened to run across them. We registered on Monday noon and then started out rather aimlessly to see what we could see. We confess that our method was not scientific, and that we should have studied the programs beforehand, and should have made out a schedule assigning every fifteen minutes of every day to a specific observation. We did not do it because no one else did it. As we wandered up and down the aisles of the registration and exhibit rooms, we met every doctor that we had hoped to meet, and every one of them was doing exactly the same thing that we were doing. If we stopped to talk with a friend, other acquaintances would join us until we blocked the aisle, and then we would separate, each headed for some exhibit, or friend, or meeting that had been mentioned. This method of seeing the A.M.A. was highly satisfactory and enjoyable, and we recommend it as the most efficient way to take in its features. After all, the physicians that one meets constitute the essence of the meeting of the A.M.A., or of any other organization.

When we registered, we received a big guide book and circulars of information—which we promptly lost,—as did five hundred other doctors on the first day of the session, according to the over-worked girl at the Information Bureau. A carrying bag with shoulder straps for the benefit of absent minded doctors was the only needful thing that was omitted by the Committee of Arrangements.

The central attraction of the meeting was the Exhibits Building. Here we went at every spare moment, here we found our old friends and made new ones, and here we saw practically everything that a doctor would use in his practice. The exhibits were of two kinds,—the commercial and the scientific. The commercial exhibits contained medical books, and surgical instruments, and X-ray apparatus, and foods, and drinks, and magic lanterns, and microscopes, and medicines, and gowns, and diplomatic demonstrators, and accommodating nurses and clerks,—everything except automobiles. We were told there were 149 commercial booths in the exhibits, and we know the aisles were packed during the entire day.

The scientific part of the exhibit was in the far end of the building, and the exhibitors were medical schools, medical societies, departments of health, and lay organizations for the promotion of health. The aisles were not so crowded as those of the commercial exhibits, and the visitors were possibly more sedate and dignified than

those who patronized the soft-drink booths, but yet we felt that the scientific exhibition was the most important feature of the whole A.M.A. meeting. The exhibits were not designed to impart instruction, as the wife of one of the doctors found when she saw a demonstration of freshly autopsied lungs and thereby lost her appetite for dinner. But the exhibits gave the physicians an idea where they could find information on any subject. The Medical Society of the County of Kings, N.Y., for example, had a modest booth illustrating the graduate education work of the Society. We met a Pennsylvania doctor there to whom the demonstrator was showing the Monthly Bulletin of the Kings County Society as a novel feature of the Society's work, and he responded by producing a copy of the Monthly Bulletin of the Lycoming County Medical Society which has only 110 members and has issued a monthly publication regularly for over five years. This is a sample of the give and take which was constantly going on in the exhibit room. In order to get the most out of the exhibits, a doctor needed to have plenty of time, and a pocket note book with which to catch the information which was freely offered to him. It beat a radio concert.

We were interested in the educational motion picture films, especially those that were produced at home in New York. Dr. Lewis Gregory Cole's film that was shown on Tuberculosis Day at the Syracuse meeting of the Medical Society of the State of New York, was also shown at Atlantic City, and we were also permitted to see a private demonstration of a companion film on gastric peristalsis. These films are to be considered in the same class as the illustrations of a book or an article in a medical journal, and we are entirely ethical in informing our readers that they may rent the films through the American Medical Films, Inc., 350 Madison Avenue, New York. Medical Societies and health organizations will find the films valuable for serious demonstrations. They will fit well into the education plans of the Medical Society of the State of New York.

The wealth of lectures and demonstrations was incredibly extensive. A large theatre over the registration and exhibition hall was in constant operation all day long on every one of the five days of the meetings. The program consisted of either moving picture demonstrations or of medical lectures illustrated with lantern slides. The subjects that were presented were of practical, every-day interest to every family physician. The amount of material presented in this room would have been considered sufficient for almost any state society meeting, but in addition scientific programs were being presented at the same time.

in each of the sixteen scientific sections of the Association. The presentation of papers read before the sections will be a major feature of the A M A Journal during the coming year.

We had planned to report proceedings of the House of Delegates, but when we reached the meeting room, the House was in executive session over a dispute between the physicians and a lay health organization. The House acted wisely in guarding against leaks of confidential information.

We are glad that we had the opportunity to attend the meeting with which the 76th Annual Session was opened. We were interested in the historical remarks made by Dr L F Donohue, President of the Medical Society of New Jersey, when he said that the number of people who come to Atlantic City for their health is greater than those seeking health in any other city in the United States. He also said that the Medical Society of New Jersey was the oldest medical society in the United States, having been founded 159 years ago. It was one of the sixteen state societies whose representatives founded the American Medical Association on March 5, 1846.

The principal feature of the evening's program

was an address by the incoming President, Dr William D Haggard, of Nashville, Tennessee, on the subject, "The Romance of Medicine." Dr Haggard spoke eloquently of the conquest of smallpox, yellow fever, typhoid,—deadly diseases that were formerly prevalent, and mentioned the heroes who, like Dr Lazear, gave their lives in research into the causes of the diseases, and in the development of the means of prevention and cure. He then developed the need of the adoption of the practice of periodic health examinations, and ended by eulogizing the family physician on whom there rests the responsibility of supervising the health of the great mass of people.

Dr Haggard's address is published in the May 30 issue of the A M A, and we advise our readers to read it.

Dr Haggard had spoken in the House of Delegates, and had advocated the adoption of an extensive system of graduate education for general practitioners along the lines that are being suggested by the Medical Society of the State of New York. It is probable that the State and the National organizations will cooperate in developing comprehensive plans for graduate education.

F O

### SCHOOL MEDICAL INSPECTORS

It is the custom of the Association of Medical School Inspectors of New York State to hold an informal dinner and conference on some evening during the meeting of the Medical Society of the State of New York. The conference this year was held in the Hotel Onondaga on May 13th, and was attended by forty physicians. The report of the meeting is packed full of good suggestions and ideas, and we are glad to give publicity to an abstract of it. We will give our impressions rather than a literal transcript of the meeting.

We are impressed with the fact that the examination of school children is the periodic health examination of the ten-year group of from five to fifteen, and that it constitutes the practice of modern pediatrics as applied to older children. It is the application of facts of general medicine to children of a certain age group, and the more general medicine, or pediatrics, the examiner knows the better will be the examination that he will make.

How much of an examination should an inspector make? Dr Haven Emerson said that it would require five dollars' worth of medical service to make an adequate examination of a school child. Dr Emerson says that five dollars is a minimum price at what a physician can make an adequate health examination of an adult, and that

the actual cost has been three dollars when an extensive series of examinations has been made by an economical institution. Of course, the standard form of health examinations is attained in very few schools.

Five cents a minute is a standard value of doctor's services in examining school children. A common rate of pay is one dollar per pupil, or if twenty minutes is given to each pupil,—more than the average time,—the price is five cents per minute. The standard suggested by Dr Emerson is two hours for each examination and charge of five dollars. The schools get just about the kind of examinations they pay for. Some want only a ten cent examination, just to comply with the law.

Dr Emerson called attention to a very obvious yardstick that could be used for measuring the effectiveness of health work in a school,—and that is the "non-effective rate", or the percentage of pupils who are absent on account of their health. This varies from one and one-half to thirteen and even more per cent. This is the same standard that is applied to workmen in factories. Few schools teachers know what percentage of absentees is due to ill health, for parents give that in place of other reasons for absence.

The examination of pupils who are mentally defective or retarded was discussed by Warren W Cox, Ph D, Chief of the Educational Measurements Bureau of the State Department of Education, and the psychiatric examination for nervous and abnormal mental states was presented by Dr C O Cheney, Assistant Superintendent of the Utica State Hospital. Doctors generally need to remember that the services of examiners in these two State Departments are available for their private cases, and that clinics in both branches may be arranged through correspondence with the Departments.

Dr Frederick Martin of Ithaca, N Y, said

that about five per cent of school children needed treatment for speech defects, and that their treatment was set forth in an article which could be obtained by application to the State Department of Education. He advocated palatal exercises for lax pillars after tonsilectomy. The exercise consists in standing before a mirror and watching the pillars contract and relax while saying "ah". This syllable is to be uttered one thousand times daily until the pillars, when at rest, assume a normal high-arched position. We fear that few children will use the exercise if it has to be done one thousand times every day.

F O

### ANNUAL MEETING OF THE NEW YORK STATE ASSOCIATION OF PUBLIC HEALTH LABORATORIES

At the ninth annual meeting of the New York State Association of Public Health Laboratories held in Syracuse on May 12th, Dr V C Jacobson of Albany was elected President of the Association. Others elected were Dr M Maslon, Glens Falls, Vice-President, Miss M B Kirkbride, Albany, Secretary-Treasurer, and Dr F E Sondern of New York, member of the Council. Dr Warren B Stone is also a member of the Council. The business meeting was followed by a scientific session at which several papers of general interest were presented.

The importance of commencing specific therapeutic treatment at the earliest possible moment in the case of syphilitic individuals was urged by Professor Wilhelm Kolle, Director of the State Serum Institute at Frankfurt-on-Main, who, as guest of the Association, delivered the principal address. While sterilization is successful in a high percentage of cases treated shortly after infection has occurred, the period during which an abortive healing is possible has been shown by animal experiments and clinical observation to be very limited, in human beings not more than four to eight weeks. After this period sterilization of the infected body is usually not possible. Prompt and vigorous treatment with the most effective remedy is therefore of the utmost importance in syphilis. The intramuscular use of mercury and especially of bismuth in conjunction with salvarsan treatment is recommended because of their power of arresting the progress of the infection while the precipitate formed is undergoing very gradual absorption in the tissues.

When using the Weil-Felix reaction as an aid in the diagnosis of typhus fever, Dr Gilbert and Miss Coleman of the State Laboratory in Albany emphasized the necessity of performing the test with the patients' serum unheated and heated to 56° C for an hour. Relatively thermostable ag-

glutinins for B Proteus X-19 were present in serum from a doubtful case with symptoms slightly suggestive of typhus fever or Brill's disease, while heating destroyed the agglutinins in two specimens of serum from typical cases of typhus fever.

The rapid development of the Montgomery County Laboratory with the Julius Wassermann Memorial, under State Aid, was described by Dr J A Dickson, the Director. The greatly increased service now rendered by the laboratory to the physicians in the county is directly due to the influence of State aid. The staff consists of six persons. The entire county laboratory work, including public health and private work and the laboratory work in the different hospitals, is carried on under one head. No charges whatever are made and the services of the laboratory staff are available at all times.

Dr Stanhope Bayne-Jones of the University of Rochester reviewed the studies of D'Herelle and others of the nature, action, and use of bacteriophage. The two theories, one that it is a living parasite of bacteria, and the other that it is a lytic ferment produced by the bacteria, were discussed as was also the importance of bacteriophage in the biologic study of bacteria and its possible significance for the study of the ultra-viruses and practical value in the treatment of certain infections.

Dr Baumgartner of Clifton Springs described the clinical and laboratory findings in seven cases of tropical sprue. It has been suggested that the disease, which is characterized by frequent large frothy stools, loss of weight and anemia, may be due to a gastro-intestinal infection with a yeast-like organism, *monilia psilosis*. This organism was cultivated from the stools of all the cases studied. It, or a similar organism, was found,

however, in a few other diarrheal anemic cases not diagnosed as sprue

A statistical review of the types of pneumococci isolated from one hundred forty-eight specimens of sputum by the Syracuse Municipal Laboratory indicated, according to Professor Jones of Syracuse, that there may be very marked variations in the relative frequency of the various types of pneumococci isolated from sputa, according to the class of patients selected, their age, geographical distribution and perhaps other factors

Dr Alvin G Foord of Buffalo reported a fatal case of botulism in a woman who died five days after eating spoiled home canned string beans prepared by the "cold pack" method six months previously, and kept meanwhile in a kitchen cupboard at room temperature. The symptoms and autopsy findings were typical *B Botulinus*,

Type B, was isolated from the beans and from the intestinal contents of the patient at autopsy. An extract of the beans and toxin produced in cultures were extremely toxic for guinea-pigs and rabbits, while chickens proved highly refractile. Complete protection was afforded by Type B antitoxin

Results of a study of variations in the alkaline tide in urine and parallel variations in gastric acidity were discussed by Dr Roger S Hubbard of Clifton Springs. In about 80% of the cases studied the results corresponded. They indicate that the tide is probably due to the secretion of hydrochloric acid by the stomach and that the presence or absence of significant amounts in the gastric juice can be shown with a fair degree of accuracy without resorting to gastric analyses

### ANNUAL CONFERENCE OF NEW YORK STATE HEALTH OFFICERS AND PUBLIC HEALTH NURSES

The Annual Conference of Health Officers and Public Health Nurses of the State will be held at Saratoga Springs June 23d to 25th inclusive

The morning session on the first day, which will be a joint session for health officers and nurses, will be addressed by Governor Smith, Dr N B Van Etten, President of the N Y State Medical Society, Dr J W S McCullogh, Chief Officer of Health, Ontario Provincial Department of Health, and Dr Matthias Nicoll, Jr, State Commissioner of Health

During the remainder of the Conference separate sessions for health officers and nurses will be held. Among the speakers will be Dr William H Park, Director of the Bureau of Laboratories, N Y City Health Department, who will

discuss the question of active immunization and serum treatment of scarlet fever, Dr Henry F Vaughan, President of the American Public Health Association, whose subject is Climatological Conditions and their effect on Health, and Dr John O Polak, Professor of Obstetrics and Gynecology, Long Island College Hospital, who will speak on The Practical Value of Prenatal Care

On the evening of Wednesday, June 24th, the N Y State Sanitary Officers' Association and the N Y State for Public Health Nursing will hold their annual dinner. Professor Robert W Moore of Colgate University will be the speaker of the evening

## RECENT ADVANCEMENTS IN CHOLECYSTOGRAPHY \*

By WILLIAM H STEWART, M D, MAX EINHORN, M D, AND ERIC J RYAN, M D

NEW YORK CITY

THE February, 1924, issue of the Journal of the American Medical Association contained an article entitled "A Preliminary Report on the Roentgenographic Examination of the Gall Bladder, A New Method Utilizing the Intravenous Injection of Tetrabrom Phenolphthalein Sodium Salt," by Drs E A Graham, W H Cole and G H Copher, of St Louis. While investigating tests to ascertain the function of the liver, the discovery was made that when certain drugs were administered intravenously the bile became opaque to the X-ray, causing the outline of the gall bladder to be clearly defined. Different dyes were used experimentally, the outcome being that the Tetrabrom Phenolphthalein Sodium Salt was found to be the most practical for routine use.

This discovery was received with enthusiasm by all the roentgenologists throughout the world. Up to this time the roentgen diagnosis of gall bladder lesions had not been satisfactory. In a fair percentage of cases, if special attention was paid to the technique, gall stones, pathological gall bladders and adhesions were recognized, but a considerable proportion remained that could not be detected.

With this new method we are now able to not only discover the pathology present, but in addition, to give some definite data as to the size, shape, location and emptying power of the gall bladder and of no small importance is the ability to study the function of the liver, recognizing delay.

The greatest achievement is the fact that gall stones which are non-opaque to the X-Ray, when surrounded by this opaque bile are outlined by negative shadows which can be readily recognized. In some cases the surface of the non-opaque stones absorb a sufficient amount of the dye impregnated bile to become visible in the roentgenograms.

It was early recognized that if, with no fault in the technique, the gall bladder shadow did not appear at any time during the frequent necessary X-Ray examinations after the injection, it was due to one of the following reasons:

### *A In cases without obstructive jaundice*

1 Obstruction of the cystic duct due either to stone or stricture. This includes cases of hydrops or empyema of the gall bladder.

2 Obliteration of the lumen of the gall bladder due to shrinkage, tumor growth or packing with calculi.

3 Thickening of the wall of the gall bladder with insufficient lumen and bile content, to cast a shadow.

4 Unusual thickening of the contents of the gall bladder (bile mud) so that it cannot mix with the recently excreted bile from the liver containing the test medium.

5 Defective liver function with imperfect excretion of the opaque bile.

*Theoretically in all other cases without obstructive jaundice the gall bladder should be visualized.*

### *B In cases with obstructive jaundice*

1 Shrunken, contracted and empty gall bladder found, according to Courvoisier's law, in the chronic intermittent form of obstruction produced by a calculus in the common bile duct.

2 Obstructions above the junction of the cystic duct with the common duct with no bile filling of gall bladder, as for example in carcinoma of the hepatic duct or carcinoma of the hylus of the liver.

3 Excessive distention of the gall bladder with bile, in common bile duct obstruction due, for example, to chronic pancreatitis, carcinoma of the head of the pancreas or carcinoma of the papilla of Vater, so that the

\* Read at the annual meeting of the Medical Society of the State of New York at Syracuse May 12 1925

admixture of the test medium is too dilute to cast a shadow

4 Arrested liver function in cases of very protracted and intense chronic obstructive jaundice due to any cases where, by continued back pressure in the biliary system, not even the normal bile is excreted into the bile ducts or gall bladder and so-called "white bile" is found at operation

Therefore, in cases with obstructive jaundice the gall bladder would most likely be visualized when the jaundice is due to a chronic progressive obstruction at or near the papilla of Vater produced by a chronic pancreatitis, carcinoma of the head of the pancreas or carcinoma of the papilla, or when it is due to the more acute form of calculous obstruction, provided the distention of the gall bladder has not been too extreme

The shadow of the normal gall bladder following the intravenous injection of Tetrabron should appear at the fourth hour, show diminished size and increased intensity at the eighth hour, become more intense in detail and less in size at the twenty-fourth hour and disappear thirty-six hours after the injection. Any variation in this sequence is strongly suspicious of pathology

Largely due to these positive findings the use of the test became general

Soon, however, objections were advanced against the method, the most serious being the severe toxic symptoms which developed in many cases almost immediately after the intravenous injection. These consisted of flushing of the face, dizziness, headache, vomiting, faintness and collapse. In some patients the condition seemed critical, nevertheless they revived quickly. Some stated they felt as well after as before the injection, others suffered from severe headache and nausea for twenty-four hours. So far as we have been able to ascertain, no deaths have been reported

Efforts were immediately made to overcome these toxic symptoms. The usual dose of 55 grams of the Tetrabrom was administered intravenously in two doses instead of one, fifteen minims of 1-1000 solution of adrenalin were given just before the first dose, and if there was much flushing of the face, five minims more were given before the second injection. The technique was also much improved, only freshly distilled water being used and the injection given slowly in the recumbent position by the gravity method instead of by a syringe. The preparation of the patient was improved upon, food being withheld for about twelve hours before the test. More care was exercised in the selection of the cases. Patients with cardiac lesions were not allowed to submit to the procedure, nor were highly hys-

terical or nervous patients considered desirable subjects

Despite these precautionary measures reactions occurred, some quite severe. This was sufficient to discourage the use of the test, that the procedure in many of our larger institutions was discontinued. However, a few, recognizing the importance of the roentgenographic visualization of the gall bladder, continued using it

In the January, 1925, issue of *Surgery, Gynecology and Obstetrics*, Drs Lester R. Whitaker and Gibbs Milliken, of Boston, published an article entitled "A Comparison of Sodium Tetrabrom Phenolphthalein with Tetraiodo Phenolphthalein in Gall Bladder Radiology." They stated that while Tetraiodo was equally as toxic as Tetrabrom the increased atomic weight of the iodine radical in Tetraiodo over the bromine in the Tetrabrom rendered it possible to obtain the same roentgenographic results with one-half the dose, and in consequence less reaction. Their deductions were so plausible that the test was again taken up with renewed enthusiasm. Observations showed that their statements were true. Patients did not have as severe reactions from the smaller dose of Tetraiodo as had been observed following the use of the Tetrabrom. A recent article by Drs Graham, Cole and Copher accepts the advantage of the Tetraiodo over the Tetrabrom and advocates the routine use of the iodine salt<sup>1</sup>

Even with the conceded advantages of the Tetraiodo there still remained an occasional unfortunate toxic experience with the intravenous injection and the enthusiasm was suspended

In February of this year (1925) the authors began to administer the Tetraiodo into the jejunum through the duodenal tube. It was found that in the average patient only 2 to 25 grams of the dye were required to satisfactorily outline the gall bladder. The tube was inserted at night, and in the early morning the exact position of the tip was ascertained fluoroscopically, if it was well down in the jejunum, the Tetraiodo dissolved in 200 cc of freshly distilled water, was slowly injected, usually in two doses, until the full amount had been given. Roentgenographic observations were then made four, eight, twenty-four and thirty-six hours after the administration. As a rule, the normal gall bladder was outlined as beautifully and regularly and showed the same time for filling and emptying as with the intravenous method. One must be certain, however, that the solution is injected well down in the jejunum, otherwise there will be a regurgitation into the stomach with vomiting. Recently articles by Drs Samuel

Weiss<sup>2</sup> and Israel O. Palefski<sup>3</sup> have appeared advocating this method.

While in a number of ways the jejunal method was found to be superior to administering the dye intravenously, it was far from harmless, many patients having severe reactions about an hour after the injection. In short, it was still a hospital procedure.

Investigations made by the authors, supported by results reported by Dr. M. Sosman, of Boston, and Drs. T. O. Menees and H. C. Robinson, of Grand Rapids, convinced us that the drug could be given by mouth, and satisfactory results achieved thereby. Considerable experience has confirmed these deductions. We now routinely use the oral method in all cases referred to our office for the roentgenographic examination of the gall bladder. The method of procedure is as follows:

After a thorough cleansing of the intestinal tract and a light breakfast, a preliminary roentgen examination of the gall bladder is made in the regular manner at about 10 a. m. The usual lunch is then allowed. At 5:30 p. m. a light meal is advised, consisting of vegetable soup, a baked potato, bread and butter and a cup of coffee, tea, cocoa or milk. Forty grains of the Tetraiodo Phenolphthalein having been freshly made into eight five-grain pills, and well-coated with keratin, the patient is instructed to begin at 9 p. m., and take two pills with a wineglass of water every fifteen minutes until all are taken. No breakfast is allowed. At 10 a. m., the following morning, a complete fluoroscopic as well as roentgenographic examination of the gall bladder region is made. Four hours later, at 2 p. m., the examination is repeated. Regular lunch is served at 2:30 p. m., followed by another X-ray examination at 4 p. m. The patient returns the following morning for a final observation.

It is essential to make the preliminary examination before the administration of the Tetraiodo for we believe that a visible gall bladder found with the ordinary method is frequently an indication of pathology. The "test" can be used as a check on these findings, for fictitious shadows have more than once been erroneously diagnosed as a diseased gall bladder.

The starvation diet is necessary in order that the gall bladder may become distended with the opaque bile. In normal cases it should appear at the twelfth hour and should slightly diminish in size and become more intense in

outline four hours later. As soon as food is given it commences to contract and to empty itself as shown by the diminution in size and detail of the shadow. This observation is to be made during the examination at 4 p. m., after lunch. The following morning, thirty-six hours after the Tetraiodo the shadow of the gall bladder, unless pathological, should have disappeared.

So far, our patients submitting to the oral method, fifty-three cases in all, have had no severe reaction. These have been seen at our private office, Lenox Hill and Lutheran Hospitals, New York City. About ten per cent had a vomiting attack and five per cent a mild diarrhea. The majority misinterpreted the use of the pills, and claimed that they did not even move the bowels. In only four cases out of the series in which the Tetraiodo was given by mouth, did we fail to obtain a gall bladder shadow. In addition, nearly all showed increased liver detail, especially of the lower border, a most important anatomical "landmark" in the interpretation of the roentgenograms.

We are convinced that the oral method is the safest and best. It is more than likely that in time it will prove to be as reliable in the roentgen investigation of the gall bladder as bismuth and barium are in the gastrointestinal tract.

It is well to bear in mind, however, that the method to be of practical value in the diagnosis of gall bladder disease must confirm and support the clinical findings. This can only be accomplished by a close cooperation between the surgeon or internist and the roentgenologist.

We are indebted to Dr. DeWitt Stetten, of New York City, for suggestions in the preparation of this paper.

## THE TONSIL PROBLEM \*

By ALBERT M. ROOKER, M.D., F.A.C.S.

NIAGARA FALLS NEW YORK

THE tonsil, which by some is regarded merely as a herniated lymph node, and by others as a detached piece of undeveloped thymus, because it looks and grows like it at first, is present in practically all our lower animals. The size, shape and position vary considerably in animals just as in humans, but the description of Barnes, I believe, is the best I have read. He says, "The tonsil is a more or less almond-shaped mass, situated between the pillars of the fauces, extending upwards usually to the origin of the pillars in the soft palate and downward to the base of the tongue. They are composed of lymphoid tissue in a rather sparse connective tissue mesh, and lie in a fossa separated from subjacent tissue by a fibrous capsule. These masses of lymphoid tissue are penetrated by numerous crypts lined by squamous epithelium, the same as covers the remainder of the tonsil, and end very near the capsule." There are about six to eighteen of these crypts—those in the upper part being wider, deeper and often branched.

Situated as it is at the entrance to the respiratory and alimentary tract—it is exposed to all sorts of infection and abrasions. The food passes over them, and squeezed by the superior constrictor and tongue muscles, particles are forced into these crypts, where it lies and decomposes, forming a perfect culture media, so that the crypts normally contain swarms of bacteria—pathogenic and non-pathogenic. As to the significance of these bacteria, any number of observers, after most exhaustive research, have obtained an equal number of different and widely varying results. Experiments with carmine granules placed in crypts with a special canula, and also rubbed on the surface of the tonsil, showed subsequently the presence of carmine granules in the sub-epithelial tissues—on the other hand Chinese ink and soot both painted on tonsils hours before tonsillectomy and also fed to rabbits with food for a week—showed none in the tonsil itself.

Virulent bacteria, however, behave differently than inert granules. Lever succeeded in infecting rabbits by painting tonsils and pharynx with virulent streptococci. The streptococci were found in both the tonsils and pharynx beneath the epithelium, and the animals died of septicaemia—but might it not have been due to a blood stream infection that the tonsillar areas became infected?

Some claim that the lymphatics convey the infection to the tonsil from the nasal mucosa and that here it is extruded into the pharynx, others do the same experiments and arrive at diametrically opposite results. What then are we to believe? Jonathan Wright speaking of his own and others' discoveries, is impressed by the fact that within the crypts of the tonsils there are constantly pathogenic organisms, which while harmless in this location, are nevertheless sufficiently toxic and virulent to produce harmful effects if injected into animals and that while dust could be and was taken up and penetrated the mucous membrane of the tonsillar crypt, while the swarms of bacteria always present were kept out, and consequently he believed that some force succeeded in differentiating toxic from harmless protoplasts—possibly something like surface tension as applied to colloids. It is possible and probable as shown by recent experiments by Mudd and Grant that this surface tension or resistance can be changed by exposure, especially to cold, by gastric disturbances, etc.

Bacterial flora varies widely—on the surface streptococcus viridans, from the crypts the streptococcus haemolyticus, and many others as pneumococcus, diphtheria, staphylococcus albus, influenza, etc. Of 113 tonsils removed for joint lesion, endocarditis and nephritis, 90 per cent were streptococcus haemolyticus.

Many systemic infections occur due to the entrance into the blood or lymph stream, either with or without primary lesions in the tonsils themselves. The normal bacterial contents of the crypts for some reason or other in certain cases is absorbed or passed through or between the epithelial cells lining the crypts, and thus gain entrance to the body fluids and then attacks that part for which they seem to have a definite affinity as streptococcus haemolyticus seems to be the organism causing most joint lesions, S. Viridans causes most endocarditis, etc. These are considered true focal infections and may occur with absolutely no symptomatic evidence of their tonsillar origin. While we have learned much about the harm tonsils may cause, what do we know of their possible use or function? Here our knowledge is largely theoretical, and at present five theories seem to be all that have any evidence to sustain their claims.

I. Theory of protection. That tonsils protect organism from bacterial invasion—this rests upon their position at the entrance to the alimentary and respiratory tract, that they

\* Read at the Annual Meeting of the Eighth District Branch of the Medical Society of the State of New York at Batavia October 13, 1924

are of lymphoid tissue and that their acute inflammation is precursor of systemic disease. The vulnerable point here is that it is ineffective, as so few bacteria actually in proportion to the enormous number ingested, really touch the tonsil at all.

II Internal secretion. No experimental proof has ever been adduced to prove this theory, which came about through the rapid enlargement of the tonsils in the first three years of life, but the large number of tonsillectomies done in recent years without producing any change in the individual except improvement, negatives this theory.

III Theory of haematopoiesis is on more solid foundation, as the follicle has a demonstrable germinal center and from this some lymphocytes are probably produced, but in proportion to the rest of the active lymphatic tissue in the body, they really are of comparatively small account.

IV Theory of elimination. This theory is that bacteria and their products are thrown off from the tonsils during septic processes elsewhere in the body. But nature never would place an organ for eliminating poisons and menacing bacteria at the entrance to the digestive and respiratory tracts, with the probability of their re-absorption assured.

V Theory of immunity is the most attractive and rational. It is that a portion of the invading organisms is held by the tonsil in its crypts and that toxins are absorbed in sufficient quantities to produce antibodies in the host. This insures an immediate auto-vaccination against the type of bacteria which are invading the organism. If this theory is true, then the tonsils are of immense value in early life until immunity is well established—then too their atrophy in later life is accounted for, and their position of vantage is explained. Then also, being at the head of a lymphatic chain which terminates in the vena cava, it is not difficult to believe that it takes on something from the pharynx and deposits it in the blood stream, and what could be more likely than that it might be a well-filtered toxin?

How are we to determine which tonsils are and which are not infected?

I History is very important. Has he ever had an attack of acute tonsillitis, no matter when or how long ago it may have occurred? Sluder says "It is very doubtful if after one attack of acute follicular tonsillitis, a tonsil ever returns to normal." Ask also if they catch cold easily and whether it begins in throat or head, ever had swollen glands as child, ever had acute articular rheumatism or other evidence of systemic infection. An affirmative answer to any of these questions is quite suggestive.

II Enlarged cervical lymph nodes, especially that one at the angle of the jaw at the anterior border of the sterno-mastoid muscle, which the patient often mistakes for the tonsil itself. Does this gland become tender—ever so slightly—at the beginning of a cold? Enlargement or tenderness here is most suggestive of tonsil infection, and is an important finding.

III Appearance of throat, and here I want to say a few words about examining the throat, which is only too frequently done in a most slipshod manner. Sometimes it is as the real estate men say, "A look means a lot," but only in rare instances is this true in regard to the tonsils. First have a good light and use a head mirror and have each in proper position before you have patient open his mouth. Use a tongue depressor with handle so your own hand is out of the line of vision, and use it most carefully. Place it not too far back on tongue, and have your middle finger under patient's chin to steady both him and your own hand, so it doesn't slip a particle, all this time telling him to take quick, short breaths and to continue doing so, for as long as his mind is on this voluntary rapid breathing, he won't gag. These simple measures if followed carefully will permit a thorough examination of the throat in nine cases out of ten. By this time you may have caught a whiff of the patient's breath, which if bad is frequently an indication of much debris in the tonsils, however, not necessarily infected, but still suggestive. Observe first the pillars—redness of the anterior pillar at its edge, when the throat is at rest, is, I believe, the most constant of all signs of chronic tonsillar infection. Compare it to the other pharyngeal mucosa—not while gagging, nor after it has been irritated by pressure, as then one gains a false idea, as redness immediately develops. Next view the tonsils (if they are not visible draw back the anterior pillar with a hooked probe, and don't say a patient has no tonsils just because they are not staring you in the face, for unfortunately patients like to believe such statements), are they large or small, and if large do they obstruct? Is there any exudate on the surface? Are the crypts numerous and are they wide open? Any debris visible in them? Any sealed in the crypts shining through the thin epithelium? Then take tonsil searcher or heavy bent probe, and press on anterior pillar and somewhat exterior to tonsil, to bring it more into view, note whether pus or debris is extruded, the thin, yellow pus is most significant, though the debris, too, may be highly infectious. This pus and debris may be examined, both smear and culture, and if found to be strep-haemolyticus, and your pa-

## THE TONSIL PROBLEM\*

By ALBERT M ROOKER, M D, F A C S

NIAGARA FALLS NEW YORK

THE tonsil, which by some is regarded merely as a herniated lymph node, and by others as a detached piece of undeveloped thymus, because it looks and grows like it at first, is present in practically all our lower animals. The size, shape and position vary considerably in animals just as in humans, but the description of Barnes, I believe, is the best I have read. He says, "The tonsil is a more or less almond-shaped mass, situated between the pillars of the fauces, extending upwards usually to the origin of the pillars in the soft palate and downward to the base of the tongue. They are composed of lymphoid tissue in a rather sparse connective tissue mesh, and lie in a fossa separated from subjacent tissue by a fibrous capsule. These masses of lymphoid tissue are penetrated by numerous crypts lined by squamous epithelium, the same as covers the remainder of the tonsil, and end very near the capsule." There are about six to eighteen of these crypts—those in the upper part being wider, deeper and often branched.

Situated as it is at the entrance to the respiratory and alimentary tract—it is exposed to all sorts of infection and abrasions. The food passes over them, and squeezed by the superior constrictor and tongue muscles, particles are forced into these crypts, where it lies and decomposes, forming a perfect culture media, so that the crypts normally contain swarms of bacteria—pathogenic and non-pathogenic. As to the significance of these bacteria, any number of observers, after most exhaustive research, have obtained an equal number of different and widely varying results. Experiments with carmine granules placed in crypts with a special canula, and also rubbed on the surface of the tonsil, showed subsequently the presence of carmine granules in the sub-epithelial tissues—on the other hand Chinese ink and soot both painted on tonsils hours before tonsillectomy and also fed to rabbits with food for a week—showed none in the tonsil itself.

Virulent bacteria, however, behave differently than inert granules. Lexer succeeded in infecting rabbits by painting tonsils and pharynx with virulent streptococci. The streptococci were found in both the tonsils and pharynx beneath the epithelium, and the animals died of septicaemia—but might it not have been due to a blood stream infection that the tonsillar areas became infected?

Some claim that the lymphatics convey the infection to the tonsil from the nasal mucosa and that here it is extruded into the pharynx; others do the same experiments and arrive at diametrically opposite results. What then are we to believe? Jonathan Wright speaking of his own and others' discoveries, is impressed by the fact that within the crypts of the tonsils there are constantly pathogenic organisms, which while harmless in this location are nevertheless sufficiently toxic and virulent to produce harmful effects if injected in animals and that while dust could be and was taken up and penetrated the mucous membrane of the tonsillar crypt, while the swarm of bacteria always present were kept out, and consequently he believed that some force succeeded in differentiating toxic from harmless protoplasts—possibly something like surface tension as applied to colloids. It is possible and probable as shown by recent experiments by Mudd and Grant that this surface tension or resistance can be changed by exposure, especially to cold, by gastric disturbances, etc.

Bacterial flora varies widely—on the surface streptococcus viridans, from the crypts the streptococcus haemolyticus, and many others as pneumococcus, diphtheria, staphylococcus albus, influenza, etc. Of 113 tonsils removed for joint lesion, endocarditis and nephritis, 90 per cent were streptococcus haemolyticus.

Many systemic infections occur due to the entrance into the blood or lymph stream, either with or without primary lesions in the tonsils themselves. Viridans causes most endocarditis, etc. These are considered true focal infections and may occur with absolutely no symptomatic evidence of their tonsillar origin. While we have learned much about the harm tonsils may cause, what do we know of their possible use or function? Here our knowledge is largely theoretical, and at present five theories seem to be all that have any evidence to sustain their claims.

I. Theory of protection. That tonsils protect organism from bacterial invasion—this rests upon their position at the entrance to the alimentary and respiratory tract, that they

\* Read at the Annual Meeting of the Eighth District Branch of the Medical Society of the State of New York, at Batavia October 13, 1924.

ications have been clean-cut and properly interpreted and the tonsils have been completely removed, I believe there is no other single surgical measure which gives such uniformly good results, and sometimes almost miraculous cures. But with border line cases, where our indications are less clear and possibly the operation has been done as a last resort in a focal infection, in these cases naturally we meet with many disappointments.

How long after operation is improvement to be expected? Occasionally it occurs in 24 hours, even in long standing cases, but this is exceptional. In an analysis of 261 chronic cases operated at the Mayo Clinic, the average length of time before actual improvement was noted was three months, and in some cases a full year passed before real improvement was observed. Kaiser in a study of 1,200 children, three years after tonsillectomy and compared

with an equal number of children unoperated arrived at the following conclusions. Children have much relief from sore throat, head colds and mouth breathing, and also lessens the chances of their having discharging ears with their complications, it assures some protection against glandular infection and materially lessens their susceptibility to contracting diphtheria—but their susceptibility to scarlet fever and measles is not influenced. Malnutrition was definitely reduced.

In conclusion I want to emphasize the importance of a careful examination, the use of palliative measures, X-Ray and suction in inoperable cases, not promising too much in border line cases, eliminating other sources of infection, and when operating to remove the entire tonsil, as a small stub can cause as much harm as the entire tonsil, and at the same time discredit both the diagnostician and operator.

## HORNELL BREAST FEEDING DEMONSTRATION\*

By B. R. WAKEMAN, M.D.

HORNELL, N. Y.

AT the May, 1924, meeting of the Medical Society of the County of Steuben, Dr. H. R. Lohnes, of Buffalo, read a paper on "Breast Feeding Recent Advances in Promoting and Maintaining the Supply." All the Hornell physicians who heard Dr. Lohnes' paper were very much interested in the subject and expressed a desire to have the topic further discussed at one of the meetings of the local medical society.

Arrangements were made with Dr. Florence McKay, Director of the Division of Maternity, Infancy and Child Hygiene of the State Health Department, to send us one of the consulting pediatricians to address the society and tentative plans were made to organize a breast feeding campaign similar to the one in progress in Long Island. Early in October, 1924, Dr. Frank Howard Richardson, of Brooklyn, addressed the Hornell Medical and Surgical Association. Dr. Richardson stated that, with few exceptions, every mother could nurse her baby provided she had proper instruction in manual expression, had the proper attitude toward breast feeding, and her physician was "sold" to the breast feeding project. See S. M. Journal p. 17. In the discussion of Dr. Richardson's paper it was pointed out that a breast-fed child is usually protected from communicable diseases and seldom suffers from digestive troubles. In an adjoining city ten babies died last summer of cholera infantum, all artificially fed.

As a result of Dr. Richardson's talk the Association, by resolution, invited the health officer to organize a breast-feeding demonstration similar to the one in operation in Nassau County, Long Island. The Division of Maternity, Infancy and Child Hygiene immediately assigned to the city, Miss Mary J. Dunn, one of the specially trained department nurses, to assist in the breast-feeding campaign.

In some respects this city is ideally suited for a demonstration such as this, in that it has a united medical profession, two well-trained public health nurses, a baby clinic, two 75-bed hospitals, each maintaining a maternity pavilion, and a training school for nurses.

Arrangements were made with both hospitals for talks to the nurses by Miss Dunn. The following lectures were given in both hospitals:

### First Talk

- a Value of Breast Feeding
- b Relation of Nurse to the Physician
- c Methods for Maintaining Breast Feeding

### Second Talk

- a Technic of Manual Expression
- b Demonstration of Expression

### Third Talk

- Difficulties of Breast Feeding
- a Those Affecting the Mother
- b Those Affecting the Baby

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 12, 1925.

tient has joint lesions, or strep-viridans, and he has endocarditis, or kidney lesion, or diphtheria, he is probably a carrier—your evidence is more complete. Sometimes, however, no pus is expressed by pressure—then I use a suction tube. This will often remove pus and debris which pressure is too painful to bring about, and sometimes an astonishing amount comes worming its way out. By now you are ready to give an opinion of the tonsil that is based upon a real examination and correspondingly valuable. But before condemning the tonsil and giving a favorable prognosis, if a tonsillectomy is done, carefully search out for other possible sources of infection, as teeth, sinuses, chronic discharging ears, gall bladder, appendix, kidney infection, prostate, seminal vesicles, pus tubes, etc. Sometimes tonsils alone do not cause all the mischief, and two foci may be at fault. I wish to emphasize this for we are so prone to jump at conclusions and remove the one focus and cease in our efforts to locate any other possible source.

Now our tonsil is infected—chronic I mean—what are we going to do with it? What are our remedies—outside of surgery—for many patients don't part with them so easily? Swabs and applications to crypts seem to be of no use whatever—at least that is my experience. Electric cauterization of crypts and slitting them open so they can discharge more readily, has also been passed into the discard by most men.

X-Ray and Radium—Recent publications by Witherbee, Craig and Hussey, and Murphy, have drawn attention to the action of X-Ray and Radium on tonsil tissue—their first enthusiastic reports have been considerably modified by other observations and the present status of this form of treatment would be about as follows. A certain percentage of tonsils treated by experienced operators may undergo more or less atrophy, and as a result of this, pathological conditions depending on retention in the crypts will improve in direct ratio to the amount of atrophy. The bacterial content of the crypts may even be materially changed, due to the improved drainage, and not to any sterilizing action of the radiation—but at present we cannot say how permanent this result may be. The method cannot take the place of surgery as was at first predicted. In both children and adults it should be advised only when an operation is contra-indicated or flatly refused. Recently in the use of suction as a diagnostic measure I noted that patients reported marked improvement in their condition after my examination, and as a consequence I wish to present for your consideration and trial, suction as a therapeutic as well as a diagnostic measure.

In applying the suction you sort of vacuum clean the tonsil, the crypts are opened wider, the pus and debris are extruded, and as a result the patient who has been suffering from a backache, stiff neck, arthritis, etc., frequently the next day reports marked improvement. I have found this so often the case, that now when I am sometimes in doubt about infection being present, I apply suction as a therapeutic test—repeating at three-day intervals and if the patient improves it is probably the tonsil but still if he doesn't improve the tonsil isn't necessarily ruled out, for suction cannot do what enucleation does. But I do want to offer this to you as being worthy of a trial especially in old people, who so often look askance at surgery, in tuberculosis, diabetes, haemophiliacs, etc. So far some of my cases have held their improvement for five months with only three treatments. It is not and cannot be permanent, but it is worthy of trial.

What are the contra-indications to tonsillectomy?

I True haemophilia. This precludes all possibility of tonsillectomy.

II Status lymphaticus. Though here the enlarged thymus might be treated by X-Ray and reduced and then be operated.

III General systemic conditions such as diabetes, and active pulmonary tuberculosis. Insulin, however, has practically restored the diabetic to the operable class. Here also could be placed acute infection of the tonsils. I usually wait until two full weeks after its subsidence, and also exacerbations of arthritic or heart conditions, though the latter by some are not considered as contraindications.

What effect on the singing voice has tonsillectomy? Provided that no undue injury is done to the palate or the faucial arches, the singing voice is not injured by tonsillectomy. However, any cicatricial contractions interfering with palato-pharyngeal movements (the muscle of the posterior-pillar) or any injury that restricts the forward and backward movements of the soft palate—has a deleterious effect—for the palato-pharyngeus tilts the thyroid cartilage on the cricoid and thereby tenses the cords and is a regulator of pitch and especially the higher notes. After tonsillectomy the voice should not be used for at least three months, and better still, for six months, as a sufficient time must elapse for the nerve fibres and muscles of the throat to accustom themselves to their new relation and position, so that they co-ordinate properly to produce the desired note.

I am not going to touch upon the operation itself, for we all have our favorite method, and I hope get good results, as far as the throat is concerned. But does the patient get the systemic relief we had hoped for? When the in-

Three apparently healthy mothers did everything they could do to maintain a supply of breast milk but failed

At the end of the first month every mother but two was nursing her baby either wholly or partially. Complementary feeding was given to 16 babies. Before this demonstration was put on "complementary feeding" was a rare thing. Previous to the demonstration much condensed milk and proprietary food was used in the feeding of babies. Now all the babies taken off the breast are placed on modified cow's milk.

A study by Barrino of Italy showed that practically half of the prematurely weaned babies were weaned during the first two weeks of life. For that reason particularly good work for breast feeding can be done with our hospital patients. During this six months' period, 57 or 46 per cent of the Hornell births occurred in the hospitals.

Active supervision of all maternity patients during the nursing period with the encouragement of breast feeding will be maintained here by the public health, hospital and private duty nurses, as long as the medical profession wishes it.

During the past three months we have had

an epidemic of whooping cough. Only one breast fed baby has contracted the disease.

### SUMMARY

The Hornell Breast Feeding Demonstration covers a period of six months, October 1, 1924, to April 1, 1925. One hundred and twenty-seven babies were born and registered for the demonstration. One hundred and six babies completed this six months' period on the breast. Of the nineteen discharged patients, thirteen did not have the benefit of the demonstration, except for the first month, for reasons cited above. Seven of these discharged babies might have been kept at the breast if we had had a little more cooperation on the part of the mothers and their physicians.

In the Long Island Breast Feeding Demonstration covering a period of two years, 92 per cent of the babies were breast fed at the end of the first month. In the Hornell Demonstration 98 per cent were breast fed at the end of the first month. Fifty-nine per cent of the Long Island mothers were nursing their babies at the nine months' period. Eighty-four per cent of the Hornell mothers were nursing their babies at the end of the six months' period.

## Deaths

ADAMS, HENRY FREDERICK, Brooklyn, College of Physicians and Surgeons of New York, 1890, Fellow American Medical Association, Member State Society. Died May 17, 1925.

ALLEN, THOMAS GILCHRIST, Buffalo, State University, Iowa, 1886, Fellow American Medical Association, Member State Society. Died May 6, 1925.

BENNETT, ALICE, New York City, Women's Medical College, Pennsylvania, 1876, Member State Society. Died May 31, 1925.

BERRY, JOHN McWILLIAMS, Albany, Johns Hopkins, 1901, Fellow American Medical Association, Fellow American College of Surgeons, Member State Society, Orthopedic Surgeon and Roentgenologist Albany Hospital. Died May 13, 1925.

BROWN, LE ROY, New York City, Vanderbilt University, 1887, Fellow American Medical Association, Fellow American College of Surgeons, American Gynecological Society, New York Academy of Medicine, Member State Society, Consulting Surgeon Woman's Hospital. Died April 22, 1925.

CLARK, FRANCIS CHARLES, Oswego, Medical College South Carolina, 1903, Fellow American Medical Association, Member State Society, Consulting Physician Oswego Hospital. Died May 11, 1925.

DOUGHTY, ISAAC LINTON, Corona, College of Physicians and Surgeons of New York, 1898, Fellow American Medical Association, Member State Society. Died May 20, 1925.

GIBSON, WILLIAM MEREDITH, Cazenovia, New York University, 1878, Fellow American Climatological and Clinical Association, Member State Society. Died May 17, 1925.

HINDSALE, ROY SEYMOUR, New York City, College of Physicians and Surgeons of New York, 1898, Member State Society. Died April 25, 1925.

LETOURNEAU, G. E., Rouses Point, Victoria Montreal, Canada, 1879, Member State Society. Died May 24, 1925.

MCGINNIS, EDWARD L'H., New York City, Long Island College Hospital, 1883, Fellow American Medical Association, New York Academy of Medicine, Member State Society, Consulting Electro-Therapist Women's and Manhattan Hospitals. Died April 28, 1925.

NICHOLS, CALVIN E., Troy, University of Vermont, 1868, Member State Society, Consulting Physician Troy, and Leonard Hospitals. Died April 23, 1925.

ROBSON, JOHN A., Hall, Albany Medical College, 1886, Fellow American Medical Association, Member State Society. Died May 11, 1925.

SCHAEFFER, JOSEPH WILLIAM, Brooklyn, Long Island College Hospital, 1897, Member State Society. Died May 3, 1925.

SUTER, AUGUSTUS WALTER, Herkimer, College of Physicians and Surgeons of New York, 1871, Fellow American Medical Association, New York Academy of Medicine, Member and Ex-President State Society. Died May 28, 1925.

SULLIVAN, JOHN D., Brooklyn, New York University, 1867, Fellow American Medical Association, Fellow American College of Surgeons, Member State Society, Surgeon St. Mary's Hospital. Died May 15, 1925.

TRIMBLE, WILLIAM B., New York City, New York University, 1891, Fellow American Medical Association, American and N. Y. Dermatological Associations, New York Academy of Medicine, Member State Society, Director Dermatology Bellevue Hospital. Died May 23, 1925.

Several physicians dropped in to hear these talks and expressed their approval of the method used in instructing the nurses. The success of a demonstration like this depends very largely on the grasp the nurses get of the subject.

The department nurse was instructed to visit each physician and get his consent before visiting any of his patients. In the Long Island Demonstration the nurse did not visit a patient until she secured a written consent from the attending physician for each patient.

In the Hornell Demonstration this did not seem to be necessary as every physician gave a blank consent to visit any and all of his present and future maternity patients. The first contact of the department nurse with the doctor is the most important part of the demonstration, for the success of the work depends very largely on the interest in breast feeding which she arouses in the physician.

Some of the comments and statements the physicians made to the demonstration nurse may be noted in this connection.

Dr One Believes that most good can be accomplished by putting the message across to the pupil nurses.

Dr Two Says that many mothers confined in the hospital are unable to nurse their babies. Highly approves of giving special instruction to pupil nurses in the proper care of the patient during the initial breast engorgement. States that in cases of breast infection, baby need not be taken from the breast unless pus is mixed with the milk.

Dr Three Believes in re-education of medical profession and laity. Many mothers are indifferent in regard to their duty of nursing their babies, and urges the nurses to make every effort to instruct mothers in methods of conserving breast milk.

Dr Four Interested and indorses breast feeding work. Does not approve of baby being kept at the breast during severe illness of the mother. Thinks it is too much of a strain on the mother.

Dr Five Would like to see method of manual expression.

Note—A premature baby, under this doctor's care, is now being nourished on mother's milk, manually expressed, and given to the baby through a medicine dropper.

Dr Six Believes that efficient follow-up work by the nurses is essential to success, as the physician has little available time to do follow-up work even in the office.

Dr Seven Suggests importance of training mothers to consult their physician frequently during the nursing period.

Dr Eight Out of town when the demonstration began. Somewhat skeptical but on going over the work in detail, finally endorsed

it. Should emphasize to pupil nurses reasons why we do not use the breast pump, and should show them the various ways of urging a disinterested baby to take the breast.

Dr Nine Feels it is unnecessary to stress on value of breast feeding. He believes everyone knows its value. Upon mentioning a few facts as to death ratio between breast and bottle babies, and the less susceptibility to contagion in breast fed babies which can be told to mothers, he was convinced that here was a real field for education.

The seven other doctors visited were all interested and were willing to do their part to make the demonstration a success.

Arrangements were made with the registrar of vital statistics to furnish the two public health nurses a weekly list of all births. This enables the nurses to make earlier contact with the new mothers. The nurses keep list of all births registered, which includes the date of birth, the date of first visit and the date of each subsequent visit with a brief note of the conditions found at each visit. The first contact is made within two weeks of birth. Normal patients are visited at least once a month. Patients having difficulty with breast feeding are visited much oftener. When the nurse finds the mother is having some difficulty in nursing her baby, she immediately notifies the physician and carries out his instructions.

As soon as the mother is able to be out, she is urged to bring her baby to the clinic at the health center to be registered, weighed and measured. This tends to conserve the time of the nurses. By contact with the clinic physician and other mothers attending the clinic the new mother's interest is still more stimulated.

During the first six months of this demonstration (from October 1, 1924, to April 1925,) 127 babies have been registered and each mother visited by the nurses. Of this number 21 have been discharged, leaving April 1st, 106 mothers who are either wholly or partially feeding their babies on breast milk.

Of the 21 patients discharged

One baby died of acute dilation of the heart at the end of two weeks.

Three have moved out of town.

Two mothers have tuberculosis.

Three mothers are non-cooperative—do not wish to be tied down to a nursing baby.

One mother in poor health, had a severe shock (father burned to death).

Four mothers anaemic, poorly nourished had some concurrent infection.

Four babies placed on the bottle by physician as it was easier.

have gathered some idea of the trend of thought of the physicians of New York State. It has been suggested that state-wide conferences be called for secretaries of county medical societies and chairmen of the local committees on economics, legislation, public health, and other committees of the county societies. A conference of each committee would involve about 70 men, and if it lasted three hours, and every man spoke, each speaker would have two and a half minutes, and if he did not speak, he may as well read a letter that is sent to him by the chairman. We believe most thoroughly in conferences, but we would like to see them held by small groups, such as those of the District Branches. The conferees in each Branch are familiar with their own problems, and as they sit around a table, they will have abundant opportunity to discuss all phases of their problems.

The District Branches need a common purpose. An evident objective is the promotion of graduate education and clinical programs of county society meetings. In order to carry on this educational work, there must be an organized machinery. The 10,000 members of the State Medical Society constitute an army under the command of General Van Etten. The District Branches are the regiments, each under a colonel—the President and Councilor. Each county society is a company under a captain—the local President. The natural and necessary system is that the General and his Staff shall reach the companies through the regimental commanders. This was the intention of the founders of the State Society, and it will probably be the plan which will be developed by the present leaders of the State Society.

### GRADUATE MEDICAL INSTRUCTION

The House of Delegates at the annual meeting in Syracuse unanimously accepted the reference reports upon the report of the special committee on graduate medical instruction. These reports not only strongly endorsed the principle and need of graduate medical extension instruction, but urged upon the Council the wisdom of putting this work into definite action and appropriating such an amount of money as might seem expedient for this purpose.

This marks a progressive evolutionary development in the work of the State Society, and is the beginning of a new era fraught with the greatest possibilities of scientific growth for the general practitioners of medicine of this State.

Wisconsin, North Carolina, and Pennsylvania have for some years carried out extension medical teaching, and in all three the reaction has been the same. Their work has shown a steady growth in interest and attendance. It is, no longer an experiment, but has become a real necessity now demanded by the physicians. Our own County of Kings has developed a plan of graduate education which has been extraordinarily successful in meeting their needs. Their methods will without doubt serve as a model for this work in other large communities of the country. The idea underlying this graduate extension instruction is to make it possible for every physician to keep in touch with the tremendous

strides of modern medical progress without neglecting the work of his practice.

Medicine has been and continues such a rapidly progressive science that the practitioners who are not in close touch with the activities of the great medical centers should be periodically reinvigorated and kept up to date in order that these great discoveries can be made available for mankind. Such continuous and effective extension education is the greatest possible contribution that can be made to public health, and is the most efficient weapon against charlatanry and quackery. The Empire State is to-day in a better position than any other state to lead the way and to make rapid advance in everything pertaining to graduate extension education its goal. The concurrence of our great medical schools and research laboratories, and our well equipped hospitals, with the leadership of the State Society, awaits only a comprehensive and well worked out plan in order to make graduate extension work in New York State of the greatest possible help to the community and aid to the physician.

Nothing more worthy in medicine is possible at this time than to make available all the great advances in diagnosis and treatment to the physician who is desirous of keeping abreast of the times.

## THE DISTRICT BRANCHES

The founders of the present Medical Society of the State of New York builded better than they knew when they devised the system of eight District Branches that should span the gap between the county medical societies and the State Society. But the plan has been merely partly developed, and along two lines only—1, the President of each District Branch is a Councilor of the State Society, and, 2, a scientific meeting is held annually in each District.

The by-laws require each councilor to visit each county society in his district once a year, but even that has seldom been done. The last annual reports of the councilors regarding

their districts averaged about 200 words, and two reports were missing.

Why have the District Branches functioned so meagerly? We were told by one of the very best of the recent councilors that he made a careful study of his district and a full report, and felt embarrassed because his report was peculiar in that it was the only one that indicated activity in any district.

Our medical surveys of counties convince us that the officers of the District Branches are ready, and eager, to work—it only remains to suggest a unified scheme of practical activities for them to follow. Our editorial duties have required us to listen in at conference meetings and private conversations, and we

he would have had not only the humiliation of an adverse verdict, but the necessity of responding in money damages

The State Medical Society having all of these things in mind and actuated by a desire to assist, encourage and protect the members of the Society in the practice of their most difficult and hazardous profession, some four years ago, after long study, painstaking inquiry and thorough investigation, instituted and set up the present plan of group insurance. It is our observation that the doctors who have been sued and who have experienced the worry and concern attendant upon an action for malpractice, have had little difficulty in appreciating the value, indeed the necessity, of participating in this insurance plan. There are in the up-State counties 3,993 doctors who are eligible for the benefits of this protection, yet we find that only 2,147 of such doctors (or 53.9 per cent) have availed themselves of this opportunity to protect themselves against the legal risks attendant upon the practice of their profession.

The State Society and your counsel, consider-

ing all of these facts, have felt it an imperative duty frequently to bring these matters before you. The doctors who have failed to avail themselves of the opportunities presented by this well-considered plan of the State Society have only themselves to blame when suddenly they find themselves in the rôle of defendants in malpractice actions. By constant reiteration of any thought one runs the risk of tiring an auditor. Nevertheless our acquaintance with conditions and with the imperative necessity, from the doctor's standpoint, of protecting himself from the financial hazard of a malpractice suit, is such as to require the frequent presentation of this matter to the profession. What a doctor decides to do, after considering the facts, of course is his own business. Our wish and desire is that no doctor who has given of his time, skill and strength to an ungrateful patient, but nevertheless is sued, will be able to assign as his reason for not having availed himself of this insurance protection that the matter had not been brought to his attention.

---

### INFECTED FINGER

The plaintiff in this action had gone to the defendant physician and upon examination he found that the index finger of the left hand was infected, and showed signs of pus. Under a local anaesthesia of novocaine, four incisions were made and the pus evacuated. He then dressed the wound and put in sterile gauze drains. On the following day the patient returned and the finger was again dressed.

A day later, upon the plaintiff's return to the doctor's office, an examination disclosed that the infection had spread and necessitated further incisions in the finger. When the patient was advised of this condition she refused to permit the defendant further to operate upon or treat her, stating that she was going to a hospital.

Nothing further was heard by the physician from this patient until the institution of a malpractice action against him, charging

him generally with negligence and carelessness in his treatment and operation upon the plaintiff, the plaintiff claiming that by reason of such negligence she sustained permanent injuries to her finger and hand.

About five weeks after the treatment by the defendant a physical examination was had of the plaintiff's finger and at that time it was found that the infection had not entirely cleared, and that a pus pocket was still present at about the end of the first phalanx. It was also found that the finger was stiff, with ankylosis of the phalangeal joints, due to the swelling and to arthritis.

The plaintiff's attorney failing to prosecute this action, a motion was made to dismiss the same for lack of prosecution, which motion was granted, and the action terminated in favor of the defendant.

By GEORGE W. WHITESIDE, Esq.  
Counsel, Medical Society of the State of New York

## MALPRACTICE SUITS—PROTECTION THEREFROM

In our editorial of April 24, 1925, we discussed the medical hazards attendant upon the practice of medicine in the metropolitan district. We shall now consider the same question in connection with the other counties or "up-State."

We there pointed out that the vast hordes of foreigners, many of them newly arrived and unfamiliar with American standards of fair play and good faith, constitute a large proportion of the litigants against members of the medical profession on charges of malpractice.

This menace to the doctor's good name is less threatening in the up-State counties containing, as they do, a far more American population and consequently imbued with American standards of ethics, and therefore less prone to the making of reckless accusations. The past decade has brought an infiltration of foreigners into our up-State cities and rural districts, many of southern European birth, which is unprecedented in our history.

Irrespective of the character of the population, the practice of medicine in up-State cities and rural districts presents distinct and serious legal hazards.

The desirability of hospital care and treatment in large classes of cases, if not in all, and the superiority of this method to such treatment as can be afforded in the ordinary home environment, is now thoroughly recognized. While it is true that in many sections doctors, with a commendable zeal for the welfare of the public health, have joined together and erected private hospitals, many of them containing the highest type of equipment and service, there nevertheless remain in various parts of the State large rural districts remote from hospital facilities. In every type of human disease or malady the likelihood of full and complete recovery is strongly dependent upon the systemic condition of the patient. The condition is dependent upon a number of factors, among which are care, food, nursing and a clean sanitary environment. On isolated farms and in small rural centers there still is found a notable lack of sanitary improvements and surroundings which complicate and increase the burden of the conscientious doctor seeking in the particular case to bring about a good result.

We have observed cases of general septicæmia—attributable wholly or in part to unsanitary surroundings, care and treatment by unskilled

assistants—where the doctor has been most unjustly blamed, where wholly unfounded and unjust charges and accusations of malpractice have been leveled against him for results in no wise caused or contributed to by his lack of care, skill or conscientious devotion to his duties. Obstetrics, perhaps, more than any other branch, has offered a fertile field for litigation due to these causes.

Both the profession and the laity today recognize the diagnostic value of X-rays in fracture cases. Yet where a fracture has occurred in some rural or isolated district many miles from a hospital or other place possessing X-ray equipment, it may not be feasible or even desirable to remove a patient before the fracture is reduced. It may well be that the value of an X-ray in such a case is counterbalanced by the disadvantage to the patient's system and condition which would be occasioned by a long and painful ride to some point where an X-ray picture might be taken. It is the doctor's duty in all cases to "use his best judgment in exercising his skill and applying his knowledge" and to do "what he thinks is best after careful examination." That is his legal duty. It may well be that in using his best judgment and doing what he thinks is best after such careful examination, he is forced to counterbalance the relative importance to a patient of an X-ray diagnosis as compared with the physical disadvantage of a long and painful journey to a point where an X-ray can be made. We have in mind a recent case in an up-State county where this exact situation occurred. The doctor was confronted with this precise problem and in view of the age and physical condition of the patient he decided that desirable as an X-ray would have been, the attendant risk of a journey to the place where it could be taken, many miles from the accident, more than offset the value of an X-ray. The patient instituted a malpractice action against the doctor, charging him with negligence in not having had an X-ray taken of the fracture. We thought that under the circumstances he was right and fortunately he was exonerated by the court. He had, however, hanging over him like a pall for many months the danger, annoyance, anxiety and worry, as well as the injury done to his reputation by the institution of the suit. This particular doctor was not insured. Had he not been successful in vindicating his course in court,

# Medical Society of the State of New York

## MEETING OF THE COUNCIL

A meeting of the Council of the Medical Society of the State of New York was held at the Hotel Syracuse, Syracuse, N. Y., on Thursday morning, May 14th, 1925

Dr Nathan B Van Etten, President, in the chair

Regrets were received from the Secretary, Dr Dougherty, who had been obliged to return to New York the previous afternoon

A quorum being present, the meeting was called to order by the President at 9 45 A. M., and on roll call the following answered to their names

Drs Nathan B Van Etten, William H Ross, Frederick H Flaherty, E Eliot Harris, George M Fisher, Owen E Jones, Andrew MacFarlane, William Warren Britt, John A Card, Joseph S Thomas, Nelson O Brooks, George H Fox, William I Dean

Dr James N Vander Veer and Dr Joseph S Lawrence were also present

On motion duly made and seconded, the reading of the minutes of the last meeting was dispensed with

The following recommendations from the President were upon motion duly made and seconded, approved

That the minutes of the previous meeting be read and after they have been approved, signed by the Secretary

That following the reading of the minutes, action be taken on the business of the preceding meeting before any new business is considered

That all discussions be limited to three minutes

That after the minutes of the Executive Committee have been approved, a typewritten copy

be sent to every member of the Council, with a request that he sign and return to the Secretary

On motion, duly made and seconded, the following recommendations were approved

That a vote of thanks and appreciation be sent by the Council to Dr Flaherty for the remarkable work he had done as Chairman of the Committee on Arrangements

That the Council send a letter of appreciation and thanks to the City of Syracuse for its hospitality

That the Council extend its sincere thanks and appreciation to the Women's Committee for the delightful entertainments which they had provided for the visiting ladies

That Dr Vander Veer be requested to reconsider his decision declining reappointment as Chairman of the Committee on Legislation and that he be given until the next meeting to decide

That Dr Vander Veer be appointed Chairman of the Committee on Legislation until the next meeting of the Council

That Legislative bills of interest to the profession be sent to the President and Counsel of the Society and that they be appointed a committee to give an opinion on them and return to the Chairman of the Committee on Legislation, who would act as the ultimate judge

On nomination of the President, Drs E Eliot Harris, John A Card, Frederick H Flaherty, William H Ross, and George M Fisher were elected members of the Executive Committee for the ensuing year

There being no further business, the Council adjourned

## MEETING OF THE COUNCIL

A meeting of the Council was held at the State Society Rooms, 17 West 43rd Street, New York City, on Wednesday, June 3rd, 1925

Dr Nathan B Van Etten, President, in the Chair, Dr Daniel S Dougherty, Secretary

A quorum being present, the meeting was called to order by the President at 3 P. M., and on roll call the following answered to their names

Drs Nathan B Van Etten, William H Ross, Frederick H Flaherty, E Eliot Harris, George M Fisher, Daniel S Dougherty, Charles A Gordon, Andrew MacFarlane, William Warren

Britt, John A Card, Joseph S Thomas, Charles P McCabe, Owen E Jones

The minutes of the last meeting were read by the Secretary and on motion adopted

The Secretary read a letter from Dr James N Vander Veer stating that, much as he regretted doing so, he felt it necessary for him to decline the position of Chairman of the Committee on Legislation for the coming year

On motion, Dr Vander Veer's resignation was accepted and the Secretary instructed to express to him the Council's appreciation of his devotion and untiring work in the interests of the State

# State Department of Health

## VALUE OF MEDICAL PROPHYLAXIS IN PREVENTING VENEREAL DISEASES

From time to time the subject of medical prophylaxis, its value and its place in venereal disease control, comes up for discussion. The State Departments of Health, with possibly one exception, have not officially applied this factor in their control measures.

The annual report of the Surgeon General of the Navy for 1924 contains some interesting information upon this subject. It is estimated that careful disinfection early applied will prevent over 50 per cent of infections that would occur without chemical prophylaxis. The rate of infection is materially reduced by the use of medical disinfection, the value depending largely upon the lapse of time between exposure and treatment. It has been concluded that

22 cases of disease per 100 exposures occur when treatment is applied within one hour,

31 cases of disease per 100 exposures occur when treatment is applied within two hours,

43 cases of disease per 100 exposures occur when treatment is applied within three hours.

Colonel Ashburn estimates (Military Surgeon, 1920) from an extensive survey in the Army, one infection in thirty without prophylaxis, and but one infection in ninety with prophylaxis.

Colonel George Walker, from observations in the American Expeditionary Forces of 240,000 prophylactic treatments, states that 13 per cent were followed by infection or one infection to seventy-seven contacts.

The report of the Surgeon General of the Army for 1920 states that "it may safely be said that venereal prophylaxis is not so efficient as to justify any man in assuming any risk of infection and counting upon its use to compensate for his lack of control, but is sufficiently effective to warrant its employment in the most thorough manner as a very important part of any campaign directed against venereal diseases."

## ACCURACY NECESSARY IN BIRTH CERTIFICATES

From time to time some of our friends among practising physicians do not see the point in our insistence on definite categorical statements in birth and death certificates, whenever the facts are known.

The following letter from an attorney in a city of Western New York will illustrate the importance of accurate records.

"I herewith return questionnaire relating to the birth of a child born January 27, 1890, to

"If the child born to

was

born alive, the father is entitled to the life use of the real estate owned by his wife at the time of her decease. If the child was born dead, Mrs.

's brothers and sisters, nephews and nieces are entitled to immediate possession and use of the property."

Our records show that the child "died at birth."

Here is one instance where a legal decision depended upon the exactness of a statement in a birth certificate.

## TRICHINOSIS FREQUENCY

The experience of the Boston Health Department indicates that trichinosis may be a more common condition and may be more often confused with typhoid fever than is generally realized. (*Monthly Bulletin, Health Dept., March, 1925*) For the last two years, the Department has, for epidemiological reasons, made extraordinary efforts to trace the source of infection in cases reported by physicians as typhoid fever. While these investigations have been undertaken usually for the purpose just stated and without any intention of confirming or disproving the correctness of a diagnosis of typhoid fever reported by a physician, they have neverthe-

less disclosed the existence of nearly twenty hitherto unrecognized cases of active trichinosis. Moreover, these cases have been disclosed because of suspicions aroused by the objective symptoms, by puffiness of eyelids or cheeks or an injected conjunctiva, presented by patients whom medical inspectors have seen in connection with their visits to trace sources of typhoid infection. Recognition of trichinosis in such supposed typhoid cases has led to the discovery of other persons likewise suffering from trichinosis, some of whom had not gone to a physician for relief.—*The Nation's Health, May, 1925*

FRAUDULENT SUBSCRIPTION

MEDICAL SOCIETY, KINGS COUNTY

When renewing my subscription to the STATE JOURNAL, I was told that \$3.50 would be deducted from my county medical society's dues. No mention was made on my statement. Will you please look into the matter and let me know.

Yours sincerely,

C. E. KRETZ

RECEIPT

Renewal for 1925, No 1047

11/24/1924

Received from Dr C E Kretz, 293 State Street, three and 50/100 dollars for NEW YORK STATE JOURNAL OF MEDICINE. Paid in advance.

L. F. WHITTAKER,

*Rep International Sales Co*

Referred to Legal Counsel

Invitation from the Medical Society of the County of Niagara to hold the next annual meeting of the Medical Society of the State of New York at Niagara Falls

Referred to the President for reply

Communication registering a complaint against a physician in Buffalo

Referred to Medical Society of the County of Erie.

The recommendations of the House of Delegates to the Council were read by the Secretary and on motions duly made and seconded, disposed of as follows

That an appropriate expression of appreciation be forwarded by the Secretary of the Society to Governor Alfred E. Smith and to other members of the Legislature mentioned in the report of the Committee on Legislation

Referred to the Secretary and the President

That the Executive Editor be directed to go to Albany during the Legislative session and spend one or more days in Albany each week at the expense of the Society

Referred to Executive Committee

That a special committee be appointed with power to put into immediate effect a plan of graduate medical extension instruction which will meet the greatest need today this committee to co-ordinate the existing medical schools and hospital staffs according to their geographical zone to the end that in and around each may be created a center for post graduate medical education, with which adjacent county societies shall co-operate in every way possible

Referred to Executive Committee to appoint at the next meeting

*Whereas*, there exists in the State of New York today, a situation which menaces the public health and threatens to undermine public confidence in the legitimate practice of medicine, and

*Whereas*, there are a large number of individuals and establishments actively opposing the best interests of the ill, the defective, and the growing youth, through illegal, deceptive and fraudulent practices, and

*Whereas*, many of these individuals and establishments appear to be operating under a system of charlatanism whose chief function is to obtain money from the unlettered, the uninformed, the alien and the ignorant through such frauds, and

*Whereas*, these conditions exist not only in every large city but in many of the small towns and villages throughout the State, thereby making this problem an issue of the State Society,

*Therefore, Be it Resolved*, that the Council properly investigate and take such measures as will correct these deplorable conditions

Referred to Executive Committee with power

That the Committee on Legislation be authorized to secure the co-operation of various groups of physicians who are not affiliated with the Medical Society of the State of New York officially

Referred to Executive Committee with power

That the Journal be sent during the Legislative Session to all legislators, newspapers published in the State, officers and members of the Executive Committees of the allied professions, State or District Societies of nurses, dentists, school medical inspectors, health officers' associations, and the like, and to a selected group of lay societies

Referred to the Executive Committee with power to investigate and refer to Council for referendum vote

That conferences be held in the Council as to certain other selected medical and educative publications which should be sent to these groups

Referred to Executive Committee with power

That legislation which has come up in the past session in reference to the State Institute for the Study of Malignant Disease at Buffalo, and the State Hospital for Crippled and Deformed Children at West Haverstraw, be referred to the Council for study and suggestions as to action for your next Committee on Legislation

Referred to Executive Committee

That the New York State Journal of Medicine be published weekly or semi-monthly throughout the year

Referred to the Executive Committee

That the services of the Executive Officer be wholly under the direction of the Committee on Legislation from the first day of December until one month after the closing of the Legislative Session

Referred to the Executive Committee

That the Committee which was appointed to study the Workmen's Compensation Law be continued, or a similar committee be appointed, and that they be directed to place in the hands of

Society, and the deep regret felt that he would be unable to continue as Chairman of the Committee on Legislation

On motion, the appointment of a Chairman of the Committee on Legislation was referred to the Executive Committee

The Secretary presented the following recommendations from the Executive Committee to the Council, which were on motions duly made, and seconded, adopted

That the report of the Budget Committee, including the tentative budget, be approved

That all appropriations for money, not included in current expenses of the Society, be made in detail to the Executive Committee for action before any indebtedness is incurred

That under Section 30 of the By-Laws the Executive Committee shall transact all the business of the Council, in the interval of the meetings of the Council

That the Executive Officer's report be accepted, the portion pertaining to medical education be referred to the Committee on Public Health and Medical Education, and the portion pertaining to scientific work be referred to the Committee on Scientific Work

That the Executive Officer's expense account for May be approved

The following amendments to the by-laws of the Bronx County Medical Society were presented for approval and on motion referred to the Executive Committee

Section 7—OFFICERS Add after Treasurer "and three Censors to represent every one hundred members, in good standing, of our Society. Censors shall be elected each year to serve for a term of two years. No Censor shall succeed himself in office. The Censors shall assume office on the first day of January following their election"

Omit Section 8.

Add to Section 14 "There shall be an Advisory Council composed of the retired Presidents of the Society whose function shall be to meet with the Comitia Minora in an advisory capacity, but shall have no voting power"

Add to Section 16 "Two meetings of the year shall be devoted to the consideration of the welfare of the members of the Society"

Section 11 Add to the list of standing committees "A Program Committee which shall be composed of three members elected by the Society at the annual election. The duty of this Committee shall be to co-operate with the President of the Society in arranging the program for the stated meetings."

Section 55 Omit the words, "and a ballot containing all nominations shall be sent to each member with the notice for the annual meeting"

Add "Additional nominations may be made at the annual meeting before the opening of the polls. Ballots should be printed having only the offices printed, but no names of candidates shall be printed"

Moved and seconded that the bill presented by Dr Lytle as a member of the special com-

mittee on the Nurse Problem be paid in accordance with the by-laws Carried

Moved and seconded that the expenses of the program guests at the recent annual meeting of the State Society be paid, but that it be done with the understanding that it was not establishing a precedent for payment in the future. Carried

Moved and seconded that the Council confer upon Miss Baldwin the title of Business Manager, and that the honorarium of \$500 recommended by the House of Delegates, be given her Carried

Moved and seconded that Mrs Delehanty be appointed Secretary of the Legislative Bureau at a salary of \$2,400 a year Carried

Moved and seconded that Dr Britt be empowered to draw up a plan of a meeting of the Chairmen of the Committees on Medical Economics of the County Societies to be held in the fall and report to the Executive Committee. Carried

On motion, Dr MacFarlane and Dr Lawrence were appointed a committee to redistrict the State with a special appropriation for maps, charts, etc

On motion, the Speaker and the Secretary were appointed a committee to draw up suitable resolutions on the death of Dr A Walter Suiter, ex-President of the Medical Society of the State of New York, and for many years Secretary of the Medical Society of the County of Herkimer

On motion, the report of the Committee on Medical Economics of last year was referred to the Committee on Medical Economics to report back to the Executive Committee

On motion, Dr E R Cuniffe was appointed Chairman of the Committee on Arrangements for the ensuing year

It was moved, seconded and carried that the next annual meeting of the State Society be held in New York City

On recommendation of the Committee on Publication, Dr Frank Overton was re-appointed Executive Editor at the same salary as last year

The following letters were read by the Secretary

ÆTNA LIFE INSURANCE COMPANY

May 2, 1925

DEAR MR. WHITESIDE

We are very anxious to reprint in pamphlet or mimeograph form your very excellent article which appeared in the April 3rd issue of the NEW YORK STATE JOURNAL OF MEDICINE, pages 577-578.

At your earliest convenience will you please let me know where you have any objection to our reprinting this article, giving you the proper credit of course.

Yours very truly,

STANLEY F WITHE, Assistant Director,  
Department of Publicity

Request granted with Mr Whiteside's consent

# MEDICAL SURVEY

## MEDICAL SURVEY, NUMBER 12—STEBEN COUNTY

**Editor's Note**—The information on which this Survey is based was given principally by Dr B R Wakeman, Secretary of the Medical Society of the County of Steuben, and Dr W W Bachman, President, and by Dr John A Conway, District State Health Officer

The Executive Editor also had the pleasure of attending a meeting of the Steuben County Medical Society, which is reported on page 848 of this issue

**S**TEUBEN County is the fourth on the lower tier of counties beginning at the west end of New York State. It has an area of 1398 square miles, and is approximately square in form. It consists principally of rolling farm land, which is used largely for dairying.

The common routes of travel are determined principally by the topography of the county. A broad, hilly tableland extends down the center of the county from the northwest to the southeast, and is bounded by two broad river valleys—the Canisteo on the west and the Cohocton on the east. Two main lines of railroad lie in the valleys—the D L & W and the Rochester division of the Erie in the east, and the main line of the Erie in the west. The principal centers of population and trade are on those railroads. The city of Corning is in the southeast corner of the county, and the village of Bath, which is the county seat, is on the same railroad in the north central part of the county. The city of Hornell is situated in the west valley, about halfway between the north and the south boundaries of the county.

Travel is easy up and down each of the two valleys, but it is difficult across the hilly country which separates them. Although good automobile roads connect the two valleys, they are often impassable during the snow season, and travel is then by long circuitous railway journeys.

The result of its topography is that the physicians of Steuben County naturally divide themselves into three groups—one centering in Corning, one in Hornell, and one in Bath. This same triple division is felt politically, for the county maintains three court houses—one in each center—in order that they shall be easily reached by witnesses and lawyers.

**Population** The population of Steuben County is 80,627, according to the U S Census of 1920, and it has been nearly stationary for over forty years. There has been about ten per cent decrease of the rural population of the county during the last forty years, and

a corresponding increase in that of the cities of Hornell and Corning. About one-fifth of the people now live in each of the two cities of Corning and Hornell, one-fifth in the incorporated villages of the county, and two-fifths in strictly rural communities.

There are thirteen incorporated villages, the largest of which, Bath, contains nearly 5,000 inhabitants, and the smallest, 300 or less.

The impression that one gets of both the cities and the rural sections is that the population is stable and well-to-do, and that Steuben County is an excellent county in which to live.

**Physicians** There are 92 physicians in Steuben County, located in 14 centers, according to the Directory of the Medical Society of the State of New York, but a careful check, made by the Secretary of the County Society, shows that 86 are in active practice. This gives one physician to every 925 persons in the county.

The physicians in Hornell, Corning, and Bath number 54, which gives a ratio of one physician to every 675 people. The physicians outside these three centers number 33, or one physician to every 1300 people. The ratio of physicians to population is not much different from that in Queens, Nassau and Suffolk counties, in each of which the ratio is about one to every 1100 persons.

There is a strong tendency of the physicians of Steuben county, as elsewhere, to congregate in the cities and larger villages. As the older physicians in the smaller places drop out of practice, no younger doctors come to take their places. Yet good automobile roads enable the physicians to give good service in every part of the county, except in the four townships in the southwest corner. There is a section ten miles in radius around Greenwood in which no physician is located, although it formerly supported two. The people in this section number about 3,000, and are mostly well-to-do dairymen, and can well support a doctor who is willing to drive considerable distances in order to reach his patients. He would also be within reach of the hospitals in Hornell.

The health authorities of Steuben County are advocating the plan that the county shall maintain an ambulance in order that the people of the rural sections may have the means of reaching a hospital during the winter season when the roads are impassable for ordinary automobiles.

the Counsel their recommendations for amendments to the Workmen's Compensation Law in relation to the medical features thereof by September 1st, 1925, in order that the Counsel may draft the proper bills for introduction, and submit them to the Council by the 1st of December, 1925, should the Council pass favorably upon their recommendation

Referred to the Executive Committee in cooperation with Dr Britt, Chairman of the Committee on Medical Economics

That the Council be authorized to request the American Medical Association to co-operate with the Medical Society of the State of New York to the end that all available material for graduate medical instruction—including teachers, charts, lantern slides, moving pictures, etc, be made available to the appropriate committee of the Medical Society of the State of New York for carrying out this plan and that the Council be authorized to appropriate as much money as they may deem expedient for the work of graduate medical instruction

Referred to Committee on Public Health and Medical Education to report back to the Executive Committee

That there be established a broad dissemination of education on public health questions through the public press by means of some one of the adjunct committees of the State Society

Referred to Committee on Public Health and Medical Education

That a Section on Dermatology and Syphilology be established

Referred to Committee on Scientific Work for further investigation and report

That some means be devised whereby articles on medical topics may be syndicated to newspapers through the editorial office of the Journal, or a press bureau to be established within one of the standing committees of the Society, from whence can be sent to newspapers, lay organizations, churches, schools and the like, authentic and interesting articles concerning the public health and the duty of the individual in relation to the health of his neighbor. Also it might be of advantage were some journalist engaged upon half or full time to help the committee upon whom such work would fall

Referred to Committee on Publication

That the Council institute legal proceedings

to prohibit such unauthorized use of the title "Doctor" by those conducting an occupation involving or pertaining to the public health

Referred to Legal Counsel for opinion

That a committee of five be appointed by the President annually, with the approval and advice of the Council, including himself and the Chairman of the Committee on Legislation, in order that a body be created which can speak with authority on allied matters of public health from all angles pertaining to the people of the State.

Held over under advisement at the present time

On motion, the recommendation that the Tuberculosis Film which was shown at the annual meeting of the State Society be reproduced at the meetings of the District Branches and County Societies, was referred to Committee on Public Health and Medical Education

The Council duly approved of the following appointments by the President

Dr Samuel J Kopetzky as a member of the Committee on Scientific Work

Dr John E Jennings, Chairman of a Special Committee of Seven with power to draft a Medical Practice Act which shall be the official bill of this Society, and be published in the September issue of the State Journal

Dr Arthur W Booth, Chairman of a special committee to work in conjunction with the committee on Medical Economics to study the problems of the nurse and report back to the Council, other members of the committee to be appointed later

Dr Britt, Chairman of the Committee on Medical Economics, nominated the following as members of his committee for the coming year

Dr C C Boswell, Rochester

Dr Henry Burton Doust, Syracuse

\*Dr L Whittington Gorham, Albany

Dr Arthur S Chittenden, Binghamton

On motion, they were declared elected

Dr Gordon, Chairman of the Committee on Public Health and Medical Education, requested that he be given more time for the nomination of his committee

On motion, Dr Gordon's request was granted

DANIEL S DOUGHERTY, *Secretary*

\* Unable to serve, Nelson K. Fromm, Albany appointed in his place

ments, but will receive most kinds of chronic diseases, except those of a contagious nature

The Corning Hospital is open to all the physicians of Corning and its immediate vicinity. It has just completed a compliance with all the conditions of the American College of Surgeons, and will be listed among those approved

*Public Health Work* The official public health work of Steuben County is done by 31 health officers whose districts comprise 2 cities, 7 incorporated villages, 26 townships, and 5 consolidated districts. There is an average population of 1,600 served by each health officer outside of the two cities.

The public health nurses employed in Steuben County are as follows

County Tuberculosis	1
Hornell School	1
Hornell Health Center	2
Corning School	1
Corning City Public Health	2
Corning Red Cross	1
Corning Industrial	1
Total	9

The city of Hornell maintains a Health Center in one of the municipal buildings. The Center is the headquarters of the Health Officer, and the center for his ordinary work. In addition, the Center is the headquarters for the following activities

1 A tuberculosis clinic once a month conducted by the Superintendent of the County Tuberculosis Hospital

2 A mental clinic monthly by the Staff of the Willard State Hospital

3 A monthly clinic in mental deficiency conducted by the State Commission for Mental Defectives

4 A venereal disease clinic conducted every Monday afternoon by the city

5 A Child Welfare clinic twice a month conducted by the city

6 A breast-feeding demonstration every month under the auspices of the nurses and committee of members of the Hornell Medical and Surgical Association. This activity is popular with all classes of people, and all mothers are proud to show their babies at the monthly inspections. Over 300 babies are on the list of the clinic

The City of Corning maintains a health center whose activities are almost like those of Hornell in scope and extent, but in addition the city conducts a weekly clinic for tonsil operations

The insane cases of Steuben County are in the District of the Willard State Hospital at Willard. This is seventy-five miles distant, and the physicians and health officers have difficulty in controlling the violent cases until they can be removed to the hospital. The Health Center of Hornell has a room prepared to receive those cases

The tuberculosis work of Steuben County centers in the County Sanatorium at Bath, of which Dr Isaac Brewer is Superintendent. It is called the Pleasant Valley Sanatorium, and has a capacity for 30 patients. Dr Brewer holds monthly clinics at Corning and Hornell, and clinics in other places as occasion requires. A field nurse is employed by the County

There is a tuberculosis committee in Hornell, and one in Corning, and another functions for the rest of the county. The committees are supported by the sale of Christmas Seals. One activity of each committee is to support a summer camp for undernourished children. Each of the three camps has a capacity for about 20 children. The general county committee also supports an executive secretary, and does publicity work through the local newspapers

*Laboratories* The county of Steuben has maintained a public health laboratory in Corning for some years, and the Board of Supervisors has recently voted to establish branches in Hornell and Bath. Each laboratory will be located in a municipal building owned by the county

*Impressions* We were favorably impressed with the physicians of Steuben County, and with their organizations. They are entirely loyal to the State Medical Society, and practically every member has paid his 1925 dues. We heard few criticisms, and the principal question was "What can we do to raise the standard of the practice of medicine?" The physicians of Steuben County take a deep interest in the newer lines of activity such as graduate education, and approve the progressive plans of the Medical Society of the State of New York

**Medical Societies** The Medical Society of Steuben County has 70 members, or 81 per cent of the practising physicians of the county. The Society is active and holds the interest of its members. It holds two meetings each year, which are attended by an average of about 30 physicians. The programs are principally scientific, and speakers are often secured from the Rochester and other large medical centers.

The County Society has recently held joint meetings with the societies of Allegany, Livingston, and other neighboring counties. It held a two-day meeting at the Willard State Hospital, at which an extensive clinical program was presented.

The difficulties of travel between the two main sections of Steuben County have led the physicians to form two local medical societies which are active in a social, scientific, and civic way. The Hornell Medical and Surgical Association was organized in 1878, and is composed of the physicians of Hornell and vicinity, and some from Allegany County. It has about 25 members, and meets on the first Monday evening of each month, and concludes each session with a supper. This Society instituted a breast-feeding campaign in the city of Hornell in the Fall of 1924, and a committee has supervised the regular visitation of every baby which has been born in Hornell during the past Winter and Spring. The activity has been originated and conducted by the physicians, with some nursing assistance from the State Department of Health. A report of this activity is found on page 831 of this issue.

The local Society has also promoted the establishment of a county laboratory.

The Corning Medical Society was similar to that in Hornell, but about a year ago it changed its name to that of the Medical and Surgical Staff of the Corning Hospital. It has about 25 members and holds its meetings on the third Wednesday evening of each month. The meetings are the staff meetings of the hospital and doctors.

The Keuka Lake Medical Association is a loose organization which originated about fifteen years ago among the physicians of Steuben and the surrounding counties. It holds a two-day meeting annually at some resort on Keuka Lake, and the date is the Thursday and Friday nearest the full moon of July. The membership consists of those physicians who attended the meeting, each of whom pays two dollars in order to pay the postage, printing, and other expenses of the meeting. The physicians bring their wives and enjoy a two-day outing, and at the same time they carry out an excellent scientific program. The average attendance at the meetings of the Association is

between two hundred and three hundred physicians. The interest shown in the Association suggests the thought that there is a great field for activity lying open to the Sixth District Branch of the Medical Society of the State of New York.

**Hospitals** Six hospitals are located in Steuben County as follows:

Name	Location	Number of beds
St James Mercy	Hornell	75
Bethesda	Hornell	50
Corning City	Corning	110
Bath Hospital	Bath	40
Steuben Sanitarium	Hornell	70
County T B (Pleasant Valley Sanitarium)	Bath	30
Total, beds		375

The total number of hospital beds available to the 80,000 people of Steuben County is 375, or 4.7 beds for each one thousand of population. This is a rather high ratio compared with that of other counties which we have surveyed.

The hospitals of Steuben County are exceptionally well equipped and managed. The St James Mercy Hospital is one of the oldest in the County. It was started in 1890 by Father James Early, pastor of the St. Ann's Catholic Church of Hornell, as the result of the death of a young man who ran out of a boarding house while he was delirious with a fever. It is managed by a board whose ex-officio members are the mayor of Hornell, the pastor of St. Ann's Church, and the Mother Superior in charge of the Hospital. It is supported in part by city funds, and is non-sectarian.

It maintains a nurses' training school with 18 pupil nurses. It has an excellent X-Ray equipment, and a laboratory in charge of a technician. It has a staff of 16 physicians, who hold staff meetings on the second Monday evening of every month. Each meeting ends with a supper given by the Hospital, and the attendance is practically one hundred per cent.

The Bethesda Hospital is located just outside the north limits of the city of Hornell. It is open to practically every physician of Hornell and vicinity who hold monthly staff meetings. The hospital has a laboratory and an X-Ray equipment, and conducts a training school for nurses.

The Steuben Sanitarium is a private institution for the treatment of chronic conditions, especially those of the heart and kidneys. It is equipped to give hydrotherapeutic treat-

The object of the treatment is to keep up the normal peristalsis of the stomach and intestine without spasm, and also to give so much food that the patient gains weight. In an ulcer patient when the stomach is empty, the normal hunger contractions become painful and cause spasm. Food produces normal regular contractions and relieves spasm. The ulcer makes the stomach irritable, and increases the peristalsis. The doctor aims to control the peristalsis by food which soothes the tender ulcer and excites slow, normal waves of peristalsis.

A standard diet for ulcer cases has a basis of milk. To this are added cereals, puddings, ice cream, bread, toast, baked or mashed potatoes, eggs (soft boiled), and cream cheese. Such foods as these are both soothing and nourishing. Coarse vegetables are omitted for the first six weeks because they tend to irritate the stomach and cause excessive peristalsis. After six weeks, vegetables and fruit are added to the three principal meals, but the frequent feeding schedule is kept up for from four to six months. Olive oil, one tablespoonful before meals, is soothing and nutritious.

As for medication, none is needed, but for the mental effect we may give bismuth in ten grain doses suspended in one dram of mineral oil before meals.

Alkalies do more harm than good, for while they reduce the acidity of the stomach temporarily, they increase it after half an hour.

The relief of symptoms is effected by dieting, a cure can be effected only by the removal of the foci of infection. This can seldom be secured at once, but patients usually have to experience several attacks before they will consent to the removal of their infected teeth, tonsils, or other infective foci.

Answers to questions

(1) Carcinoma seldom follows ulcers (estimated at 4%), but a cancer may begin as an

ulcer which was carcinoma from the outset—the so-called *ulcus carcinomatosum*.

(2) Acid regurgitation of food is usually accompanied by heartburn and is due to reverse peristalsis secondary to some reflex irritation.

(3) Epigastric pain is of two types, (a), that immediately after eating, and (b), that coming on an hour or two after eating.

A pain that comes on immediately after eating is of a reflex or nervous type, and is due to something outside of the stomach, such as an appendix, gall bladder, kidney stone, gynecological conditions, or any other condition of inflammation and irritation in the abdomen.

A pain and regurgitation that comes on an hour or two after eating is that which points to an ulcer, or to a very severe chronic inflammation of the stomach or duodenum—chronic *gastro-duodenitis*.

(4) The newer conception of inflammation of the stomach and intestine is that when one part is effected, all parts are affected. Symptoms are more apt to occur where there is a narrowed part of the gastro-intestinal tube as, for example, the pylorus, or ileocecal region, or in an organ with a small lumen, like the bile duct or appendix, but the inflammation is a general one.

(5) Too little food may cause pain in the gall bladder. Food is the natural stimulant to the flow of bile. When patients stop eating, the bile ceases to flow and is stored in the gall bladder, and there its liquid parts are absorbed, and it becomes thick and deposits cholestrin tending to form tones. Feed these cases, and the bile will flow and become thinner, the cholestrin will dissolve and symptoms will abate.

The modern method of teaching about these gastro-intestinal infections is to group them all together, emphasizing the importance of eradication of all focal infections as a curative measure and frequent feedings as a palliative one.

F O

## COLUMBIA COUNTY MEDICAL SOCIETY

Dr C R. Skinner of Hudson, Secretary of the Columbia County Medical Society, has sent us the minutes of a special meeting of his Society which contains an idea worthy of imitation by other societies. The County Society held a joint meeting with the staff of the Hudson City Hospital at 9 P M on May 19th, which was attended by 16 doctors, or 42 per cent of the members of the County Society.

We note that the plan of joint meetings with hospital staffs has been adopted in some of the counties in Michigan, and that the Lycoming County Medical Society of Pennsylvania has assumed definite obligations toward the Williamsport City Hospital. Columbia County is to be congratulated on the direct connection between

the Hudson City Hospital and the County Medical Society.

It was voted that the Society accept the invitation of the Hospital Staff that the two organizations meet jointly the 3d Tuesday of each month.

Dr J P Rupee, of the Philmont Sanatorium, described the method of collapsing the lung of the tuberculous patients by the production of artificial pneumothorax. He showed X-rays illustrating the good results of the operation when adhesions did not prevent the collapse of the lung.

Dr Skinner, Health Officer of Hudson, described his work with toxin-antitoxin among children of the school and pre-school age.

Dr Mambert, of Hudson, presented a case of hemiplegia complicated with diabetes and high blood pressure.

F O

# NEWS NOTES

## CLINICAL PROGRAMS OF THE ORANGE COUNTY MEDICAL SOCIETY

The Orange County Medical Society, which has held four meetings annually, has adopted the plan of conducting a clinical meeting each month, and rotating its place among the larger centers of population. A clinic will be held on the third Tuesday of each month at four o'clock. The Medical Society of the State of New York is assisting in arranging for the clinics as a part of the medical educational plan of the Committee on Public Health and Education, of which Dr Charles A. Gordon, of Brooklyn, is Chairman.

The first clinic of the series was held in the City Hall in Middletown on May 19th, and was conducted by Dr Blake F. Donaldson, Clinical Instructor in Medicine in the Post Graduate Medical School of New York City, on the subject of "The Heart." He based his remarks on six heart cases which had been brought by the physicians of Middletown. Over thirty doctors were present, and unanimously agreed that the clinic gave them a clear insight into the modern conception of pathological hearts.

The second clinic of the series was held in St. Luke's Hospital, Newburgh, on June 16th, by Dr A. F. R. Anderson, Clinical Professor in Gastro-Enterology at the Long Island College Hospital, Brooklyn. Dr. Andresen used as his subject a case of duodenal ulcer brought by Dr E. C. Waterbury, of Newburgh, and talked in a simple, clear way of the causes, recognition, and treatment of gastro-duodenal ulcers. We are printing the following abstract of the lecture, both for its intrinsic value, and as a model for a clinical lecture before a county medical society.

The case, a married woman, age 26, with 3 children, began to have abdominal pains about 18 months ago. The pain was under her heart, came on from half an hour to an hour after eating, and continued until she took food again. She had much gas on her stomach, her tongue was coated, and she was constipated. Her blood pressure was considerably below normal, and her urine contained much indican. She was weak and underweight and unable to care for her family.

The X-ray showed the stomach reaching into the pelvis. A diagnosis of gastroposis was made about two months ago, and a supporting belt gave her relief for a time, but the symptoms soon recurred. She has been in the hospital for about three weeks, and is gaining in weight and feeling better.

The patient is emaciated from lack of food. A complete physical examination of such a patient is important. This case has large, cryptic

tonsils from which much pus can be pressed. This condition has a bearing on her sickness.

The abdomen is flabby and wrinkled from child-bearing. It is somewhat distended with gas, but we cannot be sure from palpation and percussion whether the gas is in the stomach or transverse colon. There is tenderness in the mid epigastrium and in the right lower quadrant.

This patient has ptosis of the stomach—the X-ray shows it—but her pain is not that of ptosis, there being no real symptoms due to ptosis alone.

The important point in this woman's case is the pain, which comes late after eating and is relieved by food. A further point is that the pain has come in attacks covering 18 months.

These characteristics of the pain point to a diagnosis of peptic ulcer. The opinion is confirmed by the X-ray plates. Although only one film shows the duodenal cap, this one shows the characteristic defect and protrusion due to an indurated ulcer.

The cause of an ulcer of the gastro-intestinal tube is an infection, usually secondary to a focal infection. In this case the tonsils are the probable cause. But the removal of the tonsils may not cure the case, for there may be other foci or infection—for example, the teeth or the gall bladder, the sinuses, the pelvis or the urinary tract. Cases like this one nearly always get better for a time and then recur, unless every focus of infection is removed. The doctor or surgeon who treats them takes the credit of a cure, and then in a few months the patient gets another attack and goes to another doctor to be "cured" again.

Since a gastro-duodenal ulcer is due to infection, a surgical operation is not indicated, except for a complication, such as a hemorrhage long continued, or a perforation or obstruction.

The treatment of these cases, aside from the removal of focal infections, is dietetic. Medicine does no good, except to relieve the mind of a nervous case. The principal feature of feeding is that it shall be frequent—every two and a half or three hours—and also abundant and nutritious. Two things are to be avoided: 1, meat, and 2, coarse vegetables during the first six weeks. It is good psychology to tell the patients at the outset to eat no meat for six months.

Another item of explanation is to tell the patients that the diet acts like a salve to soothe the sore ulcer, and that the food itself is a salve and a medicine.

## CLINTON COUNTY MEDICAL SOCIETY

The semi-annual meeting of the Clinton County Medical Society was held at the Dannemora State Hospital, Dannemora, N Y, at 2 30 P M, May 25, 1925, with the president, Dr C M Burdick, presiding

The following members were present Robert, Webster, Briggs, Taylor, Sartwell, Everett, Holcombe, Ryan, McDowell, Schneider, Allen, Kosseff, Nichols, Spratt, Ladue, Rogers, and Schiff, also Dr Max Lauterman of Montreal, and Dr W L Munson of Granville, the invited guests of the Society

The minutes of the last meeting of the Society were read and approved, as were also the minutes of the intervening meetings of the Comitia Minora A report of the delegate to the State Medical Society was read and on motion ordered printed and copies sent to every member of the Society

Moved by Dr Sartwell, seconded by Dr Rogers, that the Medical Society express its sense of appreciation to Dr J G McKinney for his many years of service as Treasurer of the Society Carried unanimously

Drs Taylor and Everett were appointed a committee to draw up resolutions in regard to Dr G E Letourneau, recently deceased, and presented the following

"Resolved, That through the death of Dr G E Letourneau of Rouses Point, N Y, this Society has met a loss that only time can fill

"Of more than ordinary skill, his devotion to his work won the confidence of his patients, and his kind heart and sympathy won love As a member of this Society his opinion, when expressed, received the respect of those who heard him

"Resolved, That a copy of these resolutions be sent to his family as an expression of the sympathy of the Society, and that they be made a matter of record by the Secretary"

(Signed) W U TAYLOR,  
W H EVEREST

On motion these resolutions were unanimously adopted

## OTSEGO COUNTY MEDICAL SOCIETY

Semi-annual meeting of the Otsego County Medical Society was held in the Hotel Fennimore, Cooperstown, on June 9 The meeting was called to order at 4 30 p m Eighteen members were present

After routine business, the subject of Training Schools for Nurses in small hospitals was discussed at length Censure of those trying to drive the small hospital out of this work was passed

A committee on 'Certified Milk' was appointed by request

The secretary read letters from the American Society for Birth Control, from the Gorgas Memorial, and from the Physicians' Home, which were on motion laid on the table

A letter from Dr Page Thornhill referring to a course of obstetrics which might be given to the members of Franklin and Clinton County Societies was on motion referred to the Comitia Minora with authority to arrange for such a course

Dr Munson spoke in regard to pre-school clinics in various parts of the County for which he stated the Division of Maternity, Infancy and Child Hygiene of the State Department of Health, was willing to pay local physicians up to \$15 for their services as consultants at such clinics On motion this was referred to the Comitia Minora with the request that they co-operate with Health Officers throughout the County in securing such appointments for clinics should they so desire

Dr Burdick appointed Drs Rogers and Sartwell a nominating committee to present nominations for officers to be acted upon at the annual meeting They presented the following For President, Dr C R Hutchins, Vice-President, Dr George Allen, Secretary, Dr L F Schiff, Treasurer, Dr F K Ryan, Censors, Drs Ladue, Macdonald and Everett

The meeting then proceeded to the scientific part of the program

Dr Munson read a paper on "Differential Diagnosis," which was discussed by Drs Rogers, Burdick, Lauterman, McDowell, Ladue, Webster, Kosseff and Schiff

Dr Lauterman then read his paper, entitled, "Incidence of Syphilis and Tuberculosis as Seen in General Practice," discussed by Drs Munson, Schneider, Kosseff, Robert, Webster and Schiff

Dr Burdick expressed the thanks of the Society to our guests for their courtesy in coming to the meeting and delivering their addresses

On motion of Dr Ladue, a rising vote of thanks was extended to Dr Burdick for the hospitality of himself and his associates on the Hospital staff

The payment of traveling and necessary expenses of the Society Secretary in attendance at the meetings of all County secretaries was approved Dr Bissell gave a report of the State Society Meeting, also reported a case under his care of spontaneous expulsion of gall stones, some years after a gall stone operation, through the original wound

Dr R W Ford spoke on "Some Possibilities of Endocrinology," which led to considerable discussion

Dinner was served to the members and the visiting ladies after the Society adjourned

## STEUBEN COUNTY MEDICAL SOCIETY

THE Executive Editor had the pleasure of attending a regular meeting of the Medical Society of the County of Steuben on May 19th, while making the medical survey of Steuben County, which is printed on page 843 of this Journal, and his impressions were entirely favorable. The Society met in the Hotel Sherwood, at Hornell, with the President, Dr W W Bachman, of Plattsburg, presiding. The session was begun at noon with a social dinner, at which 40 members were present. This was an excellent plan, for it promoted good will and placed the members in a receptive frame of mind for the serious work of the afternoon.

We were interested in the reports of the representatives to the House of Delegates of the Medical Society of the State of New York, and in what they said about the proceedings of the meeting of the House which was held on May 11th and 12th in Syracuse. Dr H B Smith, of Corning, reported on malpractice defense and indemnity, and urged the members of the Steuben County Medical Society to take advantage of the insurance offered through the State Society.

Dr W J Tracy, of Hornell, reported on the action of the House of Delegates regarding the use of the title of doctor, the prescribing of alcohol, and the annual budget. He summed up his impression of the meeting of the House of Delegates by saying "The oratory was fine, the opposition to many measures was marked, and the conclusion of the session was happy." We appreciate Dr Tracy's excellent summary of his impressions of the session.

Dr L M Kysor, of Hornell, Chairman of the Legislative Committee, reported on the difficulty of reaching the legislators during the few weeks between their election and the opening of the session of the Legislature, and stated that one of the legislators from Steuben County had not voted as the physicians had suggested that he should. A discussion which followed showed that the physicians of Steuben County are alive to their opportunities and responsibilities in legislative matters.

Dr John A Conway, of Hornell, Chairman of the Public Health Committee, reported on the activity of the Society in regard to the promotion a breast-feeding campaign in Hornell (see this Journal, page 831), and the establishment of two branch laboratories by the Board of Supervisors.

The Secretary, Dr B R Wakeman, reported that only two members had resigned from the Society on account of the raise in the dues of the State Society. Our impression gained from talking with the members is that they will be satisfied with the dues, provided they can see tangible results from the expenditure of the funds.

There was a lengthy discussion regarding methods of increasing the interest in the meetings of the Society. There was an undercurrent of feeling that the responsibility rested mostly on the members and leaders of the local Society, but that the State Society could do much to instruct and advise the County Society. In our capacity as Executive Editor and Reporter of medical activities throughout the State, we suggested the adoption of clinical programs for the meetings of the county societies as we outlined in our editorial on page 818 of the June Journal.

Dr J S Lawrence, Executive Officer of the Medical Society of the State of New York, explained the relation of the Society of the State to that of the County, and offered the assistance of the State Society in any activity that the County Society should undertake.

The scientific program was of practical interest to all the members. Dr John J Lloyd, of Rochester, Medical Superintendent of the Monroe County Tuberculosis Sanatoriums, showed lantern slides illustrating the general subject of "Common Sense and Tuberculosis" to the accompaniment of a running comment on practical points.

Dr John A Conway, of Hornell, demonstrated the use of the Petroff Needle in obtaining blood for laboratory purposes.

Dr Howard L Prince, of Rochester, gave a practical talk on "Bad Surgical Risks."

The meeting adjourned at five o'clock, after a session which had continued from noon, counting the informal transaction of business and reports which were carried on during the dinner hour. A stranger attending the meeting would have been favorably impressed with the proceedings, but to us who had just made a medical survey of the County, the meeting was confirmatory of our impressions that the physicians of Steuben County are entirely alive to their opportunities, and are anxious to promote the practice of both personal medicine and of public health.

# THE DAILY PRESS

The House of Delegates at its meeting on May 11th, approved the plan of syndicating medical articles to the newspapers throughout New York State. We have expressed our views on this subject in this department of the JOURNAL several times, and have kept in close touch with the lay press through a clipping bureau that has an eagle eye for everything that contains the word health or medicine, or anything related to diseases. We have classified and arranged the articles which we have received, and all the time while we were doing it, we felt that somehow the articles were not the kind that make health messages effective. Then we considered the subject from the angle of the reader. We asked ourselves, "What phases of health interest us?" The amount of health literature is amazing, and we could spend all our time reading it and preparing articles for the press, and then we would be back where we started. We can write articles, but we can't make folks, including doctors, read them.

Now, some statistics. During the first half of June we received 381 clippings, which we classified under seven heads. The following table shows the number of clippings which we received in each group:

1 Epidemics	47
2 Medical Societies, doctors, hospitals, etc	8
3 Health Departments	116
4 Lay health organizations	72
5 Popular health articles	80
6 Quacks	8
7 Not medical	50
	<hr/> 381

This is an average fortnight, and the clippings run in about the same proportion week after week. Epidemics always make good reading. The big source of news was the epidemic of smallpox in the northwest corner of Nassau County bordering on Greater New York. Twenty-three clippings were on the subject, and 7 more were on vaccination in connection with the epidemic.

Rabies in dogs in the vicinity of New York City took 5 clippings, food poisoning, 3, and scarlet fever, 2.

The clippings on epidemics would be increased in value if more explanations of the nature of the diseases were inserted, but it is doubtful that the newspapers would find space for special information unless the epidemic was alarming.

Health departments were the source of clippings to the number of 116—the greatest number in any of our classifications. The items were on a wide range of subjects which included every activity of a department of health. They included

reports of health officers, accounts of clinics, budgets, milk ordinances, sewage disposal, and housing. We confess that most of the items had little human interest, and were routine in their nature, but still we think that the newspapers are giving the official departments plenty of space, and are writing the articles in as interesting a style as the subjects will allow.

Lay organizations were the subjects of 72 clippings. We had been under the impression that organizations of laymen that are interested in health supplied the greatest group of clippings, but at present these organizations do not seem to be supplying so much publicity matter as they formerly did.

A large proportion of the items regarding lay organizations are those on the activities of county tuberculosis committees, and the health camps which they are conducting.

District Nursing Associations also supply a considerable number of news items.

Health talks and hints were covered by 80 clippings. One-third of these were inspired by the larger health departments, especially those of New York State and City. The source of the information insures its being printed widely throughout the State. The range of subjects covered is wide, and the articles generally are well written. However, we do not believe any one can possibly comply with the ten or fourteen rules of health that are frequently repeated in the clippings. These rules remind us of the oft-repeated health hints of our early life: "To keep the feet warm, the head cool, and the bowels open."

Our criticism of the usual daily press health hints is that many are on trivial subjects. But then, if they were on serious subjects, few people would read them. "Don't waste energy on a palm-leaf fan," may not be very important advice, but it is good advice so far as it goes, and may tend to reduce worrying by those who seriously think that fanning will revive a person who faints or has heart disease.

We set aside one group for quacks and the knockers of the medical profession, but we placed only eight clippings in it, and half of those came from one publication. It is to the credit of the newspapers of New York State that they support the medical profession. The exceptions are few.

Finally we made a group of those clippings which had no concern with health or medicine. These numbered 50. The reason that these clippings are sent to us is that the eager clipper sees the word "health," and at once cuts out the whole article without reading it. One clipping was on planting flowers at the health building, and sev-

## NIAGARA COUNTY MEDICAL SOCIETY

Dr George L. Miller, Secretary of the Medical Society of the County of Niagara, has sent us the accounts of two meetings of his Medical Society. The outstanding feature of the meeting of January 13th was the inaugural address by the new President, Dr Frederick J. Schnell, of North Tonawanda. The by-laws of most medical societies provide for an annual address by the president. And Dr Schnell has set an excellent example for other societies by taking his duties seriously and preparing a practical address. He first dealt with purely local matters, mentioning efforts to increase the membership, the careful preparation of scientific programs, and the agitation for a county laboratory. He then commended the activities of the State Society advocated by Dr Owen E. Jones, President of the State Society, and mentioned three—nursing, workmen's compensation, and the chiropractic propaganda. He described two cases of injured workmen whom he treated, and although both had informed their employers in writing that they were injured and under the care of Dr Schnell, yet the Commissioner disallowed his bills on the ground that no demand had been made on the employer for the treatment. These cases were cited as evidence for the need of amending the law.

Dr Schnell also commended the officers of the State Society and in mentioning the work of Dr Vander Veer, he said: "If it is a big effort to attend a meeting once in two months, how big a sacrifice is it to Dr Vander Veer to give many hours attention to organization affairs every day? I am anxious that all officers and members of this Society give all possible aid and encouragement to the State organization. I am particularly anxious that our Committee on Medical Legislation will be one hundred per cent efficient in its duties."

Dr Schnell spoke of the irksome restrictions which were placed on physicians, but he concluded: "After all, the doctor of today is pretty

well thought of, even as well as the doctor of old was thought of. To what other profession or class of men is shown the consideration and deference that is invariably shown the doctor. In the courts, as a witness, the judges and lawyers give him preference so that he does not have to wait and waste his time, in business matters and in business interviews, we tell the business man's secretary who we are, and she says, 'are you a doctor?' and we say, 'we are a doctor,' and she says, 'just a moment, please,' and 'Mr Highup will see you right away.' Even the policeman generally overlooks our shortcomings, because he feels that we are always on errands of mercy and wants to help speed us along our way.

"Hats off, the flag goes by," thrills all with solemn pride and gladness. 'Stand aside, the doctor comes,' also thrills the doctor with pride for it tells him that those who speak and that those who heed are glad he has come, for by their action they express their confidence in the doctor's ability to meet the duties of the emergency before them. As doctors we should ever strive to merit that confidence, that trust, that faith."

It was voted that the President and the Legislative Committee inform the legislators of Niagara County regarding the attitude of the Society toward chiropractors. It was also voted that a committee be appointed to consider advertising against chiropractors. Drs Wixson, Bishop and Peart were appointed.

The following committees were appointed:  
Public Health—Drs Gillick, Spalding and Lapp.

Legislative—Drs Moore, Kerr and Fitzgerald.  
Membership and Information—Drs Guillemont, Crosby, Muller, Schoemaker and Jayne.

The scientific paper of the day was given by Dr Hoffman of Buffalo, on "New Methods of Prevention and Treatment of Scarlet Fever."

F O

## NIAGARA COUNTY MEDICAL SOCIETY

The regular meeting of the Niagara County Medical Society on March 10th at the Tuscarora Club, Lockport, President Schnell presiding.

Doctors Schnell, Moore, and Fitzgerald gave a very complete report on legislation.

Dr Schnell, our representative at Albany to the Governor's conference, gave a report upon that meeting.

The death of Dr Thomas Calladine was reported to the Society and the chair was instructed to appoint a committee to draft suitable resolutions.

It was decided to send each member of the Society a new series of form letters to be forwarded by them to their respective Senator and Representative, again calling their attention to our desires on various medical legislation.

The President announced that he had obtained Dr Frederick W. Hipwell, of Toronto, Ontario, for our speaker at our next meeting, Dr Hipwell to speak on the following subject, "The Management of Diabetics as It Applies to General Practitioners."

Owing to the prominence of the speaker and his subject, the Secretary was instructed to send invitations to all medical organizations and clubs in Western New York to this meeting.

Dr Arthur Schaefer, of Buffalo, the speaker for the evening, read an interesting paper on "Aortitis."

A vote of thanks was extended to Dr Schaeffer and the meeting adjourned to lunch.

GEORGE LESLIE MILLER, *Secretary*

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review as dictated by their merits or in the interest of our readers.

**PATHOLOGY AND BACTERIOLOGY OF THE EYE.** By E. TREACHER COLLINS, F.R.C.S. and M. STEPHEN MAYOU F.R.C.S. Second Edition. Octavo, 731 pages, 306 illustrations, 4 colored plates. Philadelphia, P. Blakiston's Son and Co. 1925. Cloth, \$10.00.

**SURGICAL CLINICS OF NORTH AMERICA.** Volume 5 No. 1, February, 1925 (New York Number). Published every other month by the W. B. Saunders Co., Phila. and London. Per Clinic Year (6 issues). Cloth, \$16.00 net, paper, \$12.00 net.

**MEDICAL CLINICS OF NORTH AMERICA.** Volume 8, Number 5, March, 1925 (Boston Number). Published every other month by the W. B. Saunders Co., Phila. and London. Per Clinic Year (6 issues). Cloth, \$16.00 net, paper, \$12.00 net.

**ARTS PEDIATRICS.** By 150 Specialists. Edited by ISAAC A. ABT, M.D. Volume 5, containing 736 pages with 127 illustrations (set to be complete in eight octavo volumes). Philadelphia and London, W. B. Saunders Co. 1925. Cloth, \$10.00 per volume. Sold by subscription.

**LECTURES ON GONORRHOEA IN WOMEN AND CHILDREN.** By J. JOHNSTON ABRAHAM, C.B.E., D.S.O., M.A., M.D., F.R.C.S. 12mo of 142 pages illustrations. London, William Heinemann. 1924. Cloth, 7s. 6d.

**INSULIN IN GENERAL PRACTICE.** A Concise Clinical Guide for Practitioners. By A. CLARKE BEGG O.B.E., M.D., Ch.B., M.D. 12mo of 130 pages illustrated. London, William Heinemann. 1924. Cloth, 5s.

**PNEUMONIA.** Its Pathology, Diagnosis, Prognosis and Treatment. By the late R. MURRAY LESLIE, M.A., B.Sc., M.D. Edited and revised by J. BROWNING ALEXANDER, M.D., M.R.C.P. (Lond.). Octavo of 351 pages. London, William Heinemann. 1924. Cloth, 4s. 2s. 6d.

**THE MEDICAL YEAR BOOK AND CLASSIFIED DIRECTORY.** 1925. Second Annual Issue. Edited by CHARLES R. HEWITT. 12mo of 596 pages. London, William Heinemann. 1925. Cloth, 12s. 6d.

**THE THEORY AND PRACTICE OF THE STEINACH OPERATION WITH A REPORT ON ONE HUNDRED CASES.** By Dr. PETER SCHMIDT (Berlin) and an Introduction to the English edition by J. JOHNSTON ABRAHAM, C.B.E., D.S.O., M.A., M.D., F.R.C.S. (Eng.). 12mo of 150 pages. London, William Heinemann. 1924. Cloth, 7s. 6d.

**THE NATURE OF DISEASE.** By J. E. R. McDONAGH, F.R.C.S. Part 1. Royal octavo of 327 pages, with illustrations. London, William Heinemann. 1924. Cloth, £3. 3s.

**A COMPEND OF GYNECOLOGY.** By WILLIAM HUGHES WELLES, M.D. 5th Edition revised and enlarged, by WILLIAM BENSON HARER, M.D. 12mo of 371 pages, with 167 illustrations. Philadelphia, P. Blakiston's Son and Co. 1925. Cloth, \$2.00.

**TEXTBOOK OF DIFFERENTIAL DIAGNOSIS OF INTERNAL MEDICINE.** By M. MATTHEWS, M.D. Authorized translation of the fourth German edition with extensive additions by I. W. Held, M.D., and M. H. Gross, M.D. Royal octavo of 908 pages with 176 illustrations. Phila., P. Blakiston's Son & Co. 1925. Cloth, \$12.00.

**X-RAY ATLAS OF NORMAL AND ABNORMAL STRUCTURES OF THE BODY.** By ARCHIBALD M'KENDRICK, F.R.C.S. (Edin.), D.P.H. F.R.S.E., Surgeon-in-Charge Surgical X-ray Department, Royal Infirmary, Edinburgh, and CHARLES R. WHITTAKER, F.R.C.S. (Edin.), F.R.S.E., Assistant Lecturer Anatomy, Surgeon's Hall. William Wood & Co., New York and Edinburgh. 1925. Price \$10.00.

**LABORATORY DIAGNOSTIC METHODS.** PATHOLOGICAL, BACTERIOLOGICAL, SEROLOGICAL AND CHEMICAL. A manual for physicians, medical students and laboratory technicians. By JOHN A. KOLMER, Professor Pathology Graduate School of Medicine, University of Pennsylvania and Fred Boerner, Associate in Bacteriology Graduate School of Medicine, University of Pennsylvania. D. Appleton and Co., New York, 1925.

**PYE'S SURGICAL HANDICRAFT.** A Manual of Surgical Manipulations. Minor Surgery, and other Matters connected with the work of house surgeons and surgical dressers. Edited and largely rewritten by W. H. CLAYTON-GREENE, C.B.E., B.A., M.B., B.C. (Camb.), F.R.C.S. (Eng.). Ninth Edition, fully revised. Illustrations. Vel de minimis curat chirurgicus. William Wood and Co., New York, 1924. Price, \$7.00.

**LEPROSY.** By SIR LEONARD ROGERS, M.D., F.R.C.P., F.R.C.S. (Retired). Physician and Lecturer, London School of Tropical Medicine, and ERNEST MITT, M.D., F.R.C.S., Edin., Research Worker in Leprosy School of Tropical Medicine and Hygiene Calcutta. Illustrations. Map showing world distribution of Leprosy. William Wood and Co., New York, 1925. Price \$4.75.

**GYNECOLOGY FOR NURSES.** By M. J. SEIFERT, A.B., M.D., F.A.C.S. Attending Surgeon and Gynecologist, Columbus Hospital, Chicago. D. Appleton and Co., New York, 1925.

**ESSENTIALS OF IMMUNOLOGY FOR MEDICAL STUDENTS.** By ARTHUR F. COCA, M.D. Octavo of 194 pages, 16 plate illustrations. Baltimore, Williams and Wilkins Co., 1925. Cloth, \$3.50.

**PRACTICAL CLINICAL PSYCHIATRY FOR STUDENTS AND PRACTITIONERS.** By EDWARD A. STRECKER, A.M., M.D., and FRANKLIN G. EBAUGH, A.B., M.D. Octavo, 375 pages illustrated. Philadelphia, P. Blakiston's Son and Co., 1925. Cloth, \$4.00.

**NEWER METHODS OF OPHTHALMIC PLASTER SURGERY.** By EDMUND B. SPAETH, M.D., F.A.C.S. Octavo of 258 pages with 168 illustrations. Philadelphia, P. Blakiston's Son and Co., 1925. Cloth, \$5.00.

**THE HEALTH-CARE OF THE BABY.** A Handbook for Mothers, Nurses and Physicians. By LOUIS FISCHER, M.D. 15th Edition, completely revised, rewritten and reset. 12mo. Cloth. 267 pages. \$1.00 net. Funk and Wagnalls Co., New York.

**SIMPLIFIED NURSING.** By FLORENCE DAKIN, R.N., Inspector of Schools of Nursing, State of New Jersey. Illustrated. J. B. Lippincott Co., Phila.

eral were on the alleged illegality of hiring a hundred or two lay inspectors by the New York City Health Department. But we are not concerned about the inclusion of useless clippings so much as we are about the omission of essential ones. Clipping bureaus fail to catch a large proportion of important medical items.

A discussion of the group of clippings relating to purely medical matters has been left to the last. We have included in these clippings items regarding physicians, medical societies, and hospitals. This group includes just 8 clippings. Here is where physicians are weak. The meetings of County Medical Societies is excellent news for all the county newspapers. Do the County Societies invite the reporters to their meetings? Do the officers go to the reporters and give them the news items? We think not. They do not always send the items to the *NEW YORK STATE JOURNAL OF MEDICINE*, much less to the lay press.

Dr Vander Veer has repeatedly called the attention of the members of the Medical Society of the State of New York to evidences which come to the Committee on Legislation revealing the appalling ignorance of people generally regarding the basic facts on which medicine is founded, and the result is that people run off to those who promise impossible cures. The point is that people have little conception of the earnestness and honesty of physicians generally, and of their intense desire to prepare themselves to serve humanity. Witness the immense growth of the movement for graduate medical education. We believe that newspaper publicity can be well given to the broad activities of the Medical Society of the State of New York, especially to its educational plans.

This whole subject of popular medical education of the people is new. Neither departments of health nor health organizations of laymen have solved it, but that is no reason why the Medical Society of the State of New York should not attempt its solution.

We have frequently stated that an essential procedure is that the local County Medical Societies and smaller groups should seize occasions as they arise, and prepare articles for their local papers. There must be a timely news subject in order that the article shall make an impression on the people. The people don't care much about the health limits of Moses, but they do care about the proposal of Moses Jones to sue the town of Dewville for maintaining a smelly public dump beside the highway. Then the local editors will be glad to print health articles on smells, and rats, and decaying matter, and flies, and other things connected with garbage disposal.

What can the State Medical Society do in the way of publicity? It can sponsor articles on such subjects as graduate education, the proposed Medical Practice Act, medical economics, and other major activities and can syndicate them as departments of health do. It will cost money to send out some 1,200 copies each week.

Is this plan worth trying? The House of Delegates has submitted the problem to the Council.

Other State Medical Societies are wrestling with this problem of medical publicity. The *Journal of the Michigan State Medical Society*, June, 1925, page 324, contains a statement by the Editor, Dr F C Warnshuis, telling what subjects he thinks should be considered in medical publicity. It reads:

"The plan that I conceive—I don't know as I can give you all the light—I conceive medical publicity to be of an educational type, to convey to the public that there is such a thing as a germ and that germs produce disease, to convey to the public the means and measures by which an individual is afflicted or becomes afflicted with tuberculosis, and the means and measures that have been proved under modern scientific investigation and experience to be the curative ones. Also to convey to them the foolishness of trying to palpate or manipulate any vertebrae or rub on any kind of medicine in the form of a liniment and buying any electric pad or belt, or taking any sort of concoction that somebody may have gotten up, that is not effective. To acquaint them with the truths in medicine, as to the cause, the course and the means that are proving available for the treatment and relief of physical ailments."

Dr Warnshuis believes in giving publicity to the basic facts of medical practice, and we believe he is right. But we wonder how far we can get in our teaching. We have had somewhat to do with the teaching of hygiene in the public schools, and in the making of syllabi and texts and we have made careful estimates of the subjects that must be covered. We found that the necessary topics numbered at least forty, and that there were about ten subdivisions under each topic, and these were only hygienic topics with nothing about medicine.

We believe it to be worth while to prepare a series of articles, say fifty, along text book lines, only in a more lively style, that shall set forth the basic principles of anatomy, physiology, hygiene, and medicine, and then to offer them to the daily and weekly newspapers under the sponsorship of the Medical Society of the State of New York.

VOL 25, No 19

NEW YORK, N Y

AUGUST, 1925

## PRELIMINARY REPORT OF PRIMARY CARCINOMA OF THE CERVIX UTERI TREATED WITH RADIUM IN THE WOMAN'S HOSPITAL IN THE STATE OF NEW YORK \*

By LILIAN K. P. FARRAR, A B, M.D., F.A.C.S.

NEW YORK CITY

IN February, 1919, the Board of Governors of the Woman's Hospital, upon the request of Dr. George Gray Ward, the Chief Surgeon of the hospital, purchased 250 milligrams of radium salt. The present report is based upon the use of this amount of radium in cases of cancer of the cervix uteri in the past six years and is presented by the kind permission of Dr. Ward with whom I am associated and under whose supervision all the ward cases come and who has directed the dosage and personally seen the cases in the Follow-up Clinic. The ward cases were from the beginning assigned to the first division in the hospital to which Dr. Ward is the Attending Surgeon, in order that the dose of radium should be uniform, and this report includes all the ward cases of cancer of the cervix treated with radium and also the private patients of Dr. Ward and my own patients as I have employed the same dosage and technique. The private patients of other physicians are not included merely from the desire to know what the results are by the present methods of treatment. Radium alone, either in a tube or in needles or both together (Illus 1 and 2—C and D) has been the only treatment given the cases upon whom this preliminary report is based. A Wertheim operation has been done after radiation in several cases, but the follow-up of the end results will appear in a later report. X-ray treatment together with radium we have not used at the Woman's Hospital until the past six months and these cases are too recent to be included in this paper. This report then includes all classes of primary carcinoma of the cervix—the early, borderline or advanced, who were treated with radium alone.

*The Preparation and Dosage.*—The radium salt is in a glass capsule (100 mgms) which is contained in a silver tube, which is in turn placed in a brass tube 1 mm in thickness. This brass tube when ready for use is put into a hollow rubber

tube. We have found the rubber ink container of fountain pens to be of sufficient thickness (1 mm) very inexpensive and of suitable length for use. The open end of the rubber tube is securely tied by two strands of braided silk approximately 16 inches long and these are tied to two strands of silk previously drawn through the eyelets in the brass tube, thus ensuring the recovery of the brass tube should by any chance the rubber tube be torn in removing the radium (Illus 1-A). After sterilization in alcohol for ten minutes of the rubber covered tube containing radium, the ends of the silk are tied to an 18-inch piece of  $\frac{1}{4}$ -inch gauze (which is to be packed in the cervical canal if wide enough to permit doing so) and this in turn is tied to a two-yard strip of two-inch gauze which is to be used to distend the vaginal canal (Illus 1-B). One of these strands of silk is threaded into a needle which passes through the cervix, after the tube containing the radium is placed against the carcinomatous growth in the cervix to ensure the radium remaining in position, and this strand of silk is held taut by the assistant while the vagina is tightly packed with the wide gauze to keep the bladder and rectum as far from the radium rays as possible (Illus 2-A). When the vagina is packed this silk is wiped carefully with iodine and fastened to the vulva orifice (2-A). The intern in removing the radium needs only to cut this stitch at the vulva and pull out the wide gauze, the narrow gauze must follow and then the radium, should the patient get out of bed before it is time for the radium to be removed the tube can not be lost as it is securely tied to the vulva. The patient is prepared as for a vaginal operation and general anesthesia is given usually nitrous oxide gas is sufficient. It is thought advisable to give a general anesthetic to facilitate a thorough examination of the pelvic organs for frequently what seems to be an early case of carcinoma is found to belong to the advanced class, and also to pack the vagina more fully with gauze as the freedom of irritability of bladder

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 13, 1925.

# BOOK REVIEWS

**A TEXT-BOOK OF PRACTICAL THERAPEUTICS** With Especial Reference to the Application of Remedial Measures to Disease. By HOBART AMORY HARE, B Sc., M D, LL.D., Nineteenth Edition, enlarged, thoroughly revised 1061 pages, 144 engravings, 8 plates Phila, Lea and Febiger, 1925 Cloth, \$7 00

Dr Hare's text-book has been enlarged and rewritten, and, as a result, is more in accord with modern practice. Especially noteworthy are the diagrams illustrating the chief actions of the important drugs. Any book that goes through nineteen editions should be able to present the subject of Therapeutics in an informative and accurate manner, and this book may be cited as one that does this in a most readable way.

The modern therapist cannot consider his library complete unless it contains a copy of this book.

M F D

**DISEASES OF THE RECTUM AND PELVIC COLON** By MARTIN L. BODKIN, M D, F A C S, New York. Illustrated Second Edition, Revised and Enlarged E B Treat & Co, New York, 1925 Price, \$6 00

The second edition of Diseases of the Rectum, by Dr Martin Bodkin, compares very favorably with other books on the same subject. The general arrangement of the book, the type and paper used, are excellent. This edition contains several new chapters and a number of new illustrations. The chapter on Intestinal Flora will undoubtedly cause much discussion and all the statements may not be accepted. One would expect a chapter on the technic of the use of local anesthesia in the treatment of anorectal diseases in a new work on diseases of the rectum.

The book may be recommended to the student and general practitioner as an authoritative work on diseases of the rectum.

CHARLES GOLDMAN

**A TEXT-BOOK OF GENERAL AND SPECIAL PATHOLOGY** By J MARTIN BEATTIE, M A, M D, and W E CARRIEGIE DICKSON M D Second Edition, in two volumes Octavos of 1084 pages, with 498 illustrations and 17 plates London, William Heinemann, 1921 31/6 net per vol

This work is presented in two attractive volumes of 500 pages each, one of which is devoted to general and the other to special or regional pathology. Vol I is a masterly presentation of the fundamentals of pathology. Step by step the reader is led from a study of the cell in health and disease through the various reactions of tissues to injury, such as degenerations and infiltrations, necrosis and gangrene, atrophy, disturbances of circulation, inflammation and repair, the granulomata and hypertrophy and hyperplasia. There are many fine illustrations some in color, which aid the descriptions. Several chapters are then devoted to neoplasms, following which are chapters on animal parasites, immunity and fever. Because of the clear presentation and the attention to fundamentals, this would make an excellent text-book for medical students.

Vol II deals with the pathology of special tissues. The reviewer would particularly commend the account of the diseases of the circulatory system and blood-forming organs with the beautifully illustrated description of bone-marrow pathology, the remarks upon suprarenal pathology and the fine article upon kidney pathology. The chapter on diseases of the nervous system stands out because of the full consideration given this often neglected subject. It contains a description of the specific pathology of lethargic encephalitis.

Although there are many textbooks upon pathology,

this is a valuable addition to the list. The authors are pupils of the late Professor Greenfield, for many years professor of pathology at the University of Edinburgh where the first chair of pathology in Great Britain was established.

E. B. SMITH.

## MEDICAL CLINICS OF NORTH AMERICA.

Published every other month by the W B Saunders Company, Phila and London Per Clinic Year (6 issues) Cloth, \$16 00 net, paper, \$12 00 net.

Volume 8, Number 2, September, 1924 (Chicago Number) This number continues the high standard of these clinics. There is difficulty in selecting the most instructive articles in this number as the field is so thoroughly covered. The article by Byfield on the 'Diagnosis of Splenomegally with Hematemesis,' together with Abt's "Case of Aleukemic Leukemia with Clinical Symptoms of Plastic Anemia," gives much information on the difficult subject of the anemias and function of the spleen. Reports of pyloric stenosis in infancy, cardiospasm, peptic ulcer, mucous colitis, multi-ocular cysts of the pancreas and primary carcinoma of the liver cover thoroughly the digestive tract. Mix gives an excellent picture of the slow development of a chronic nephritis in a patient whom he was able to observe over a period of fourteen years. The efforts to prevent heart disease are given in Hamburger's article on the Prevention of Heart Disease and articles on Cardiac Aneurysm and Cardiovascular Syphilis cover the circulatory system. This issue contains a fund of useful information for the practitioner.

H M M.

Volume 8, Number 3, November, 1924 (Philadelphia Number) Much is given in the small space of this volume. Each paper is valuable, full of information, carefully written and thoroughly presented. Mohier in his article on Digitalis points out some of the unexpected results in the use of this drug and gives attention to the cases in which the drug does not act or gives unfavorable results. Riesman concisely presents a lecture on Pneumonia, with special reference to diagnosis and treatment, in which he has reviewed much of the subject in a brief article. Diabetes and its treatment is reviewed and cases presented. To realize how much there is in this issue, one must study the articles.

H M M.

Volume 8 Number 4, January 1925 (Mayo Clinic Number) The present number follows the usual scope and method of handling of the Medical Clinics of North America. There are forty-two contributors and the topics chosen are diversified and of current interest.

HENRY M FEINBLATT

**AIDS TO PSYCHIATRY** By W S Dawson, M A., M D, Oxen, M R C P Lond, D P M, Senior Assistant Medical Officer, Maudsley Hospital, Nervous Diseases. William Wood and Co, New York, 1924 Price, \$1.50

This book is a safe guide for those who would like to rapidly survey the field of psychiatry. Though brief it will give the general practitioner a very reliable idea of mental diseases. The chapter devoted to the legal aspects of insanity gives the law as applied in Great Britain. For American readers, the value of the book would be enhanced if a few notes on American rules of evidence and procedure were added. We are glad to recommend the book as scientific and carefully written.

dium action is exerted on proliferating connective tissue. For the first time in the history of medicine we are in possession of an agent which will control the growth of connective tissue."

"From the study of much material, from operation and autopsy, in cases treated by deep radiation I have become convinced that the clinical results are *not* usually due to the direct killing effect of radiation but are generally brought about indirectly and mainly by interference with the circulation—capillary venous, arterial and lymphatic. In many cases the main part of the destruction has been caused by occlusion of blood vessels."

In an admirable article by Dr. John Clark and Dr. Keen of Philadelphia, the healing process in the cervix after radium application is described as, "First, local destruction, then a considerable fibrous and tissue formation, with an ultimate condensation cicatrix followed by more or less hyalinization." To the latter process Dr. Clark says, "We attribute the chief possibilities of a cure. To thrive, cancer requires vascularization on its frontier zone. A hyaline or fibrous barrier is therefore an effective block against the invasion of new blood vessels and serves excellently in the process of incarceration or segregation of malignant cells." Dr. Clark quotes Dr. McCarty of the Mayo Clinic as laying especial emphasis on the beneficence of the latter processes in the retardation or starving out of cancerous growths. We know that there are few blood vessels in dense scar tissue and in order that cancer cells should thrive, there must be a sufficient blood supply at its border. Cut off that blood supply and cancer cells are isolated.

If we watch for six to eight weeks the clinical process going on in cervical cancer that has been treated with radium we see

- (1) A hyperemia of the tissues
- (2) A local destruction or breaking down of tissue and profuse purulent discharge with more or less absorption and possibly toxic symptoms if the destruction of tissue is great or the patient cachectic
- (3) A local sloughing area in the cervix
- (4) A diminishing slough in the cervix and a beginning healing process going on around the margins of the cervix
- (5) Complete healing of the cervix, which is now red and hyperemic, and there is now a complete disappearance of the slough
- (6) Finally complete cicatrization with marked contraction of the tissue of the cervix which is now shrunken, firm in consistency and pale in color. Until this stage is reached we do not consider the patient has had sufficient radium.

#### DOSAGE

The initial dose of radium has been 100 milligrams in a single tube placed within the cervix and left for 24 hours, with needles if there is involvement of the vagina, bladder or rectum. In young women under 30, in whom cancer cells are more resistant, the dose has been 100 milligrams for 30 to 36 hours. We have used this dose for all types of cancer cells and for all classes of involvement of the cervix by cancer considering it to be merely a *therapeutic* or *test dose*, and have been guided in subsequent treatments in the case by the result obtained by this initial dose. *Every case of cancer* of the cervix is a *study by itself*. There can be no uniform dose in successful treatment of cancer. Cases with the same type of cell and same stage of involvement by cancer vary greatly in their response to the initial dose. What is sufficient to cause a complete disappearance in one case and no recurrence for a five or six year period, is not sufficient to retard the growth for six to eight weeks in another case exactly similar to the first as far as the local lesion appeared. We know that radium has a selective action on tumor cells and that a dose of radium sufficient to hold in abeyance a malignant growth will not injure normal cells. We therefore do not try to give a killing dose to the tissues, believing, to quote Dr. Ewing again, "that ideal radium therapy seems to require a nice adjustment of relations between destructive effect on tumor cells and stimulation of stroma cells." In further support of the view that radiation therapy tends to employ and support nature's method of healing, rather than by prolonged radiation to produce such extensive tumor necrosis that the patient dies from hemorrhage or septic absorption from the decomposition products of the tumor, producing, as Dr. Ewing states, those rapid ter-

ILLUSTRATION I

Technique of the application of radium tube and needles in carcinoma of cervix

(a) Radium salt in glass and silver capsule with 1 mm brass and rubber screening. Note the tying of the silk threads, one with needle ready to anchor to tissues, and one to be attached to gauze packing

(b) Silk threads from tube and needles knotted together and tied to gauze packing

(c) Radium tube in situ in cervical canal and needles outside the cervix in adjacent tissue. Note anchoring suture passing through the cervix to be attached to the vulva

(d) Front view showing needles under the bladder and in the utero-sacral ligaments and in the broad ligaments posterior to the midline to avoid the ureters and blood vessels

and rectum depends in great measure on the distension of the vaginal canal. Early in the use of radium we found the nurses were obliged to call an interne at night to remove the gauze packing in the vagina in order to catheterize the patients who were unable to void. We then placed a mushroom catheter in the bladder (Illus 2-B) when the radium was introduced into the cervix to keep the gauze undisturbed in the patient and the internes undisturbed in bed, with satisfaction to both parties.

A punch is used to remove several pieces of tissue for pathological diagnosis before the radium is placed *in situ* and care is taken to injure the tissue as little as possible. It has been found by experience that cases treated with radium do better if preliminary care is given to the general health before administering the radium. If a patient is suffering from anaemia we have found it advisable to give a blood transfusion before

the radium and if the general resistance seems low to try rest and tonic treatment for a few days previous to administration. There is always a local destruction of tissue by the radium and by throwing into the system more toxins a marked prostration may follow from which a patient is slow to recover. We permit patients to sit up as soon as the nausea is over which is often when the radium is removed or the next day, and then let them get out of bed even though running a temperature, believing they have better drainage and absorb less by so doing. Douches of potassium permanganate are started the day after the radium is removed to flush out the purulent discharge and patients are told to douche daily after leaving the hospital. Patients are urged to live out of doors and make an effort to gain weight as we believe the beneficial effect of radium depends in part on the general body resistance. There must be a comeback in the tissues to get results from radium.

Since our recent compiling of end results the work of the radium follow-up cases has been placed under

the direct supervision of the head of the Social Service Department and a card index is being made of the housing conditions of each patient. We believe a great deal can be accomplished in this way to get favorable results in the cancer cases.

Before I speak of the dosage I would like to take a moment to consider the effect of radium salts on carcinomatous tissue and consider just what it is we hope to accomplish by giving a case of cancer of the cervix radium treatment, and upon what we base the dosage.

I will quote freely from a recent article, "An Analysis of Radiation Therapy in Cancer," by Dr. James Ewing, than whom I know no better authority in pathology. Dr. Ewing says "One can extricate and emphasize one principle of radiation therapy—viz., that radiation is capable of restraining the growth of tumor cells without causing either autolysis or necrosis" and "Ra-

## THE SPECIALIST AND THE GENERAL PRACTITIONER \*

By MATTHIAS NICOLL, Jr, M.D.,  
State Commissioner of Health

ALBANY N. Y.

IN bidding you welcome to this, the Twenty-fourth Annual Conference of Health Officers and Seventh Annual Conference of Public Health Nurses of the State of New York, I desire to express for myself and members of my staff the sincere appreciation of the loyal co-operation of the health officers and nurses with the work of the State Department of Health.

The relationship between the Department and the medical profession throughout the State continues to be most cordial. It is to be expected that the essential viewpoint of the medical practitioner and of those engaged in official public health work may occasionally lead to misunderstandings and differences of opinion. As regards the more important questions of policy and prerogatives in the fields of medical practice and public health, such difficulties as arise are becoming more readily soluble by frank and open discussion between those affected, and the number of such difficulties shows a notable tendency to decrease.

In spite of assertions to the contrary made by the ignorant, irresponsible and vicious-minded, the vast majority of the medical profession of this State, and, indeed throughout the country, stand ready at all times to defend against attack and uphold laws and regulations for the protection of the public health, not infrequently at the expense of their personal interests, and I trust and believe that the time is not far distant when the State Medical Society and the State Department of Health will be amalgamated in some closely-knit and effective organization in which the general public shall have membership and take an active part, and which shall have for its object the upholding of scientific medicine, the preservation of the public health and their successful defense against the constantly increasing number of the enemies of public welfare. That this is not impossible of realization is readily attested by the example set by the State of Washington, with which I hope that all of you will become familiar.

Physicians as a rule are poor politicians and worse lawyers, and whether they be engaged in medical practice or in official public health or both, as is usually the case among our local health officers, their work is in the definite interest of the public welfare, and that public which is the ultimate beneficiary should in simple justice bear at least a part of the burden of upholding the tenets and practice of scientific medicine.

So much has been spoken and written regarding the constantly decreasing numbers of general practitioners and the causes thereof that I have not the time nor is it necessary to dwell extensively on the many factors which are bringing about this most unfortunate state of affairs. I say unfortunate, for the reason, as I have frequently stated, that with the present organization of the public health work of the State it is to the general practitioner that we must look for the accomplishment of far-reaching results, and, it is the personal influence of the general practitioner among his patients and friends upon which we must count to a very large degree for the upholding of scientific medicine, upon which depends the prevention of disease and its proper care and treatment. The specialist, largely on account of his infrequent personal contact with the patient and consequent lack of intimate knowledge of the peculiar problems which have a bearing upon mental and physical health, is not by any means in as strategic a position to produce results as is the family physician. No more important problem confronts the people of this State and nation than that of regulating the practice of the specialties and of restoring the number and the personal prestige of the general practitioners! To that end may I be permitted very briefly to suggest certain definite means.

I am firmly convinced that the State should prohibit the practice of a specialty, in which I would include surgery, until a physician has practiced general medicine for a term of not less than five years and has qualified himself by training and experience according to established standards requisite for the competent practice of the particular specialty which he desires to undertake.

No one can dispute the fact that those, however, eminent and skillful in the more restricted specialties, with the necessarily closely-confined attention to the pathology affecting a part of the body, usually become less and less cognizant of the inter-relationship between the functions and abnormalities of other organs, even that affecting directly or indirectly conditions which may be found within their own particular field. How often do we see a patient who can afford to go the rounds treated piecemeal by one specialist after another and failing to find relief from a kaleidoscopic array of symptoms, for which in the last analysis only that physician with a broad general knowledge of medicine—and

\* Read before the Annual Conference of Health Officers and Public Health Nurses—Saratoga Springs N. Y. June 23, 1925.

minimal extensions of the disease which many observers have regarded as acceleration of growth from the stimulating effects of radiation.

A patient leaves the hospital usually at the end of a week, later if her condition is not satisfactory then, and reports to the Follow-up Clinic in one month, and from then on makes one visit each month to the clinic. If at the end of eight weeks from the first radium treatment a pale cicatrix has not formed or healing is not definitely progressing in the cervix, a second radium treatment is advised. The same dose is given or the dose is increased, according to the response to the initial dose, remembering that subsequent doses need to be greater to overcome the resistance offered by the scar tissue now formed in the cervix. In cases who do not show satisfactory retrogression of the cancerous involvement we give a third or even fourth treatment, increasing the dose as seems advisable, and some of the best results have been in cases having several treatments. Perhaps the reason for this success may be, to quote again from Dr Ewing, "Tumor tissues undergo progressive fibrosis, but usually groups of tumor cells persist in the scar tissue and later give rise to recurrence."

When one proceeds in deep therapy on the theory that therapeutic results depend not only upon injury to tumor cells but also upon defense reaction of the body and the tissues, the immediate results seem to be almost equally striking, the end result is often more satisfactory and the treatment is conducted with less damage and danger to the patient."

### RESULTS

The co-operation of the patients in the Follow-up Clinic has been remarkable, over 90 per cent of the patients have reported regularly and of the remaining 10 per cent or less, the Social Service Department has been able to trace all but eight by home visits, visits to friends of patients, and by visits to the Board of Health to inspect the list of the death certificates for the year.

It is now six years since we first began radium treatment in the Woman's Hospital and from February, 1919, to February, 1923, 196 patients have been treated, and deducting eight cases the number to be reported on is 188. I have deducted the eight cases instead of calling them dead, as recently in reviewing our Follow-up, six patients whom we had on the list as dead, as they had not reported in the Follow-up in 1½ to 4 years, walked into the clinic, every patient well and clinically free from carcinoma. So I have

stopped killing them and will report only the cases seen as being fairer to the statistics. Forty cases are in the 2 year period, 12 cases had radium and operation, and 3 cases were secondary carcinoma, so the number to be reported is 133. Since 1919, there are four periods of three years each, and I will take up these three year cases, reserving the five year cases for the report to be given at the end of the month at the meeting of the American Medical Association, as the list is not yet completed. This report includes all classes, grouped according to Schmitz classification of primary carcinoma of the cervix uteri.

Classes I and II are the operable cases

Classes III and IV are the inoperable cases

The tables are as follows

THREE-YEAR END RESULTS OF PRIMARY CARCINOMA OF THE CERVIX TREATED WITH RADIUM

Years	Classes I and II				Classes III and IV				
	No.	Traced	Living	P. C.	No.	Traced	Living	P. C.	Total
1919	11	10	4	40	32	31	7	22	268
1920	7	7	7	100	26	24	10	41.6	548
1921	9	8	6	75	21	21	7	33.3	448
1922	7	6	6	100	26	26	11	42.3	531
Total	34	31	23	74.1	105	102	35	34.3	436

All Classes I to IV 133 cases traced, 58 cases living, 43.6% total per cent

### CONCLUSIONS

- 1 Every case of cancer of the cervix uteri should be studied individually
- 2 The successful result does not depend entirely upon the direct killing of cancer cells but also upon the cicatrization of the cervix and occlusion of the blood vessels
- 3 The first dose of radium should be a therapeutic dose.
- 4 The subsequent dose should depend upon the amount of healing and cicatrization seen six to eight weeks after the initial dose.
- 5 Repeated doses of radium may be necessary to arrest the tumor cells persisting in the cicatrix.
- 6 Since results of radium treatment depend also on the defense reaction of the body and tissues every effort should be made to secure the patient a favorable environment following the treatment, and especially have we found it advantageous to use blood transfusions as an aid to this end

so-called specialties which never should have left their hands, I am firmly convinced that it will go far toward increasing the confidence of the family physician in his own powers, and the confidence of his patients in his ability to afford them relief from physical and mental suffering

Finally, may I express the earnest hope that not only in the proposed post-graduate courses but in the undergraduate medical curricula much greater emphasis be placed upon the practice and possibilities of so-called physiotherapy. We all know more or less of the value of local applications, of heat and cold, of vapor, of baths of various kinds, of massage, of electricity, of sunlight and its modifications, and the important influence of climate, yet how much attention does the average physician give to this field and how frequently he loses an opportunity to relieve suffering and thereby earn the gratitude of a patient by failure to make use of other measures of bringing relief and frequently effect-

ing a cure than by the administration of drugs. Physiotherapy is a legitimate and valuable part of therapeutics. It should be studied and practiced extensively by the medical profession and not distorted and metamorphosed into misleading absurdities, relegated so frequently to unscrupulous, ignorant and venal charlatans. In our zeal for the spectacular and the performance of one of the medical miracles made possible by recent discoveries of specific remedies let us not forget that the cases in which they are applicable make up but a very small part of the conditions for which people seek medical advice. Cling fast then to the faith of our fathers in well-established and simple measures of treatment which so often bring comfort to the patient. Study and apply the forces of nature which we are only now beginning to understand, and do not forget that medicine is not only a science but an art which requires much more for its successful practice than casual examination and the writing of a prescription.

## ADDRESS AT THE ANNUAL CONFERENCE OF HEALTH OFFICERS AND PUBLIC HEALTH NURSES\*

By N B VAN ETEN, M D,

BRONX NEW YORK

*Commissioner Nicoll, Ladies and Gentlemen*

I am grateful for this opportunity of meeting the Health Officers and Public Health Nurses of the State of New York, because I am desirous of further developing the already cordial relations between the State Department of Health which you represent and the Medical Society of the State of New York.

Most of you are members of the State Society, all of you can render valuable aid in the attainment of our common ideals.

Your Commissioner has maintained a generous attitude toward all honest practitioners of healing arts, and especially toward organized medicine.

Your Commissioner has asked the medical profession of the State to inform him of their desires for the service of his department, has met their wishes more than half way, and in return has requested specific co-operation in public health work under departmental regulation. He has been most sympathetic toward graduate medical education, and has demonstrated it by practical performance, through the employment of regional consultants, in real courses of instruction carried directly to groups of physicians who desired them.

Possessed of administrative ability, plus the liberality, toleration, breadth of vision which

should always be the background endowment of a student of sociology, your Commissioner is giving full measure to the people of this State and to the medical profession.

The history of the State of New York reveals just one Governor who has sufficiently realized that the medical profession is pre-eminently qualified to express reliable opinion on Public Health.

The first advisory conference of representative physicians of the State was called by him. Governor Smith is really humanly interested in the happiness, health and efficiency of the elements that comprise the citizenry of the State. He earnestly desires to extend the efforts of the State in disease prevention, in the salvage of the crippled, and in the comfort of the incurable.

State institutions are insufficient, overcrowded, and growing in a diminishing ratio to necessity and demand. The Governor has a vision which he desires to realize, and his laudable ambition is to advance it now, and pass on to his successors the means to develop it. Safeguarded by a proper annual budget, it is a business project which would be taken up by any large industrial organization without hesitation.

Governor Smith has always favored our medical legislation, differences of opinion among ourselves have defeated it. While we still have such a potential ally, it surely behooves the medical

\* Delivered at the Annual Conference at Saratoga Springs  
June 23, 1925

who is becoming more difficult to find—can furnish effective advice, care and treatment

With the great increase in the number of specialists there seems to be growing among general practitioners a too firm dependence upon their advice, with a consequent disparagement of their own powers and abilities. No one has greater respect and admiration for the work and accomplishments of specialists in the various branches of medicine. To a very large extent they have been responsible for the great growth of scientific knowledge along particular lines, but I confess to a sense of resentment and a strong conviction that it is not for the public welfare that the field of the general practitioner should become year after year more restricted and to an absolutely unjustifiable degree. Just as an advancing army depends for success upon the work of outposts, scouts and observers, so must the medical profession for progress depend upon the work of the specialist and research worker, but the army can not win battles save by the efforts of the men in the ranks, nor can medical science successfully combat disease and death except by the work of the enlightened general practitioner.

There can be no question that a scientifically trained physician who devotes himself exclusively to one of the more restricted specialties is more competent to produce results in his chosen field than the general practitioner. On the other hand, in the case of such broad specialties as pediatrics, tuberculosis, and, if I may add, public health, while unquestionably the leaders in those fields have been responsible for the tremendous growth of knowledge which has taken place, such knowledge contains no element of mystery, requires no superhuman intellect, and should be placed at the disposition of and obtained by every general practitioner throughout the State. I have yet to find a reason to believe that any physician in full possession of his faculties and a desire to learn, can not, when properly instructed and within a comparatively short time, become perfectly competent to undertake the feeding of infants on the most approved and scientific basis, make a diagnosis of incipient tuberculosis, or recognize and care for the average case of acute infectious disease. Except in a comparatively small number of cases, in which the patient should be turned over to the specialist during his entire illness, in my opinion his subsequent care and treatment may usually be better conducted by an up-to-date general practitioner to whom the patient and family are personally known.

Other elements which go to make up these specialties might well be cited as definitely within the sphere of the family physician, and

this is equally true as regards the fundamental principles of diseases of the heart, kidneys, blood vessels, venereal diseases, and certain conditions which are so frequently relegated, without due consideration, to the surgeon.

I am very glad indeed to learn that the New York State Medical Society, following the example of a number of other states, is about to undertake a campaign of post-graduate medical education. The State Department of Health for a number of years has been doing what it could in this field through courses for health officers in preventive medicine and demonstrations and lectures by its regional consultants in pediatrics and obstetrics. In cooperation with county medical societies and at their invitation a series of very successful lectures and demonstrations, notably in Jefferson and St. Lawrence Counties and on Long Island, have been given, which have met the approval and elicited the deep interest of the local medical profession. The Department stands ready to continue this work, at least for a time. An increased number of regional consultants will be placed at the disposal of county medical societies who desire this service, together with such nursing and laboratory facilities as may be required. We shall, however, make no effort to instigate invitations. This, I believe, should be undertaken by the State Medical Society.

I am convinced that post-graduate medical education should be undertaken by the organized physicians of the State for their own benefit, and also for the benefit of the health and welfare of the people of the State. The time to inaugurate this work is now. The physicians of the State, especially in the more isolated counties are, I believe, not only ready but eager for this service. If anyone doubts this fact, in order to be convinced he has only to study the attendance at the few post-graduate courses that have been given, and the truly remarkable interest that was shown in the tuberculosis and other exhibits at the recent meeting of the State Medical Society.

Many details, financial and others, will have to be worked out in order to make this work effective, and the State Department of Health may be counted upon by the State Society to help in every way possible to insure success. It is a wonderful opportunity and a fruitful field of endeavor, and if as a result the general practitioners of this State—especially those who are far removed from medical centers and whose attention to the arduous duties of general practice will not permit them to visit such centers for a sufficient length of time—are granted adequate facilities for keeping abreast with the latest developments in scientific medicine so that they are competent and willing to take over again such elements of the

preventive medicine They should receive sufficient salary for comfortable maintenance, and then should carry the spirit of service and co-operation to the people, always urging consultation with their own physicians if they have them, and assisting the local physician in meeting daily and emergency problems The local physician should derive ethical material help and constant educational stimulus from such contacts

The Journal of the State Society is at your service We have been carrying State Health Department news for the past two years and we want you to use this medium for reaching the medical profession as freely as you please We have, with the cordial assent of your Commissioner, drafted one of you Dr Frank Overton, who serves us, and you, as our Executive Editor He has a receptive ear, a willing pen, and an earnest desire, from his health officer viewpoint, to turn the whole state society into public health activities "Civic Medicine," in large type, is his slogan, a truly healthy idealism which deserves a real following not only from the ranks of health officers but also from general medicine His medical surveys of counties and cities of this state have attracted wide attention and have furnished valuable informative material not only to the country at large but very often to physicians in the locality surveyed who were astonishingly ignorant of their own potentialities

Everybody practices medicine "Antiseptic Charlie," the barber, pours learned advice into your ear while he holds a gleaming razor at your throat The bootblack prescribes while he polishes your corns The cultist openly invites consultation with the title "Dr" on his sign At every contact you are told what is good for you and a very natural confusion results, which can only be clarified by a constant unrelenting stream of information distributed by every health agency and especially by a State Department which speaks with authority

Physicians and nurses are all idealists or they would not have entered their chosen fields In the varying degrees permitted by their human qualities, the spirit of service dominates them all All of them desire fruition of the seeds they now sow, but many of them think they are so busy with the infinite detail of their own daily work that they do not try to see a wider prospect or realize that their influence may extend beyond what they consider is their limited sphere As large numbers of our citizens do not vote on election day, so a considerable number of physicians and nurses are not interested in organized medicine or organized health agencies Physicians should assume their rightful leadership in all civic activities concerning the public health In counties where lay organization work of the tuberculosis type has been most successful it has been headed by the active medical members of the organization The citizen who does not vote

and the doctor who is not a member of his county society and who does not attend medical meetings has small social value and is a load on his community We should not, however, despair of waking him, we should do everything we can to show him the value to himself of becoming a real cog in the machinery of progress Another type, the doctor who is only happy when he is dropping monkey wrenches in the works is more valuable because he is awake He is a potential worker if directed and possibly merely requires adjustment

#### THE NURSE PROBLEM

When I think of the nurse problem I am reminded of the label on a certain bottle which carried these instructions, "do not put raisins in this and stand it in the sun, because it will ferment"

The nurse question seems to be an economic one which is chiefly concerned with supply and compensation Enfranchised woman very naturally is descending to the level of the male citizen from the spiritual heights she once occupied, really a more or less idealistic, largely fictitious, position of domination which men created in order to make her think she was happier than they The woman in industry is now a competitor for real wages and can no longer be contented with less than she thinks she can earn or with less than is given to a man for the same quality and amount of work The higher her educational qualifications the larger her appraisal of her value It is perfectly natural and can not be denied

One of the largest industries in New York, which employs a large number of girls and women, requiring small educational qualifications and taking all of the women they can get, foreseeing the end of their proportion of the female help of the country, are installing machines for the replacement of some of these female workers by a smaller number of highly paid experts and still employing all of the women they can get The labor life of a girl in this company is two years Another great industry employing a large number of women with no educational qualification is leaving the New York metropolitan area because the end of their proportionate supply of female help is in sight They are distributing their business into small plants, placed in small towns throughout the country where there is still a supply of women who can work in the factories and live at home

The complaint that nurses desert their profession for matrimony is silly Of course, they do and of course they should Once a nurse always a nurse is a well known saying If every family included one person trained in nursing arts the domiciliary problem would be measurably solved There is no question of the value of educating as many women as possible in the art of nursing, but it may be unwise to carry their education as

profession to present a united front this year upon our legislative program. The future may not be so kind to us.

Last year a new office was created in our State organization, and we drew upon the State Health Department for a man who has been very valuable to us in stimulating all of the general activities of the society, in carrying the messages of the state officers to the component county societies, in developing friendly relationships with legislators, in promoting the various phases of preventive medicine and medical education, in studying the relationships of Health Officers and Public Health Nurses and local practitioners and lay organizations, and in making valuable studies of every problem which was presented to him. The resultant of nearly a year's work has placed the society in possession of information which gives it a decidedly advantageous start at the beginning of a new administration. Our Executive Officer, Dr. Lawrence, has also greatly stimulated our cordial relations with the State Department of Health.

Is it not largely true that most of us are largely responsible for whatever happens to us, for our just deserts? When we consider the proportion of physicians to population, 1 to 770 in the state, in many counties 1 to 1,000 and 1 to 1,200, there seems little excuse for failure of any competent physician to earn a comfortable living if he has personality, plus industry, plus appreciation of his patient.

The failure of the doctor to study anthropology, to study the whole individual, to measure proportion, to note, in detail, external evidence, to penetrate beneath the surface, to visualize pathology, to appraise subjective symptoms, to carefully search for infected foci, to study internal secretions, to always investigate excretæ, to sympathetically study psychology, indifference in these important observations has developed dissatisfaction, restlessness and loss of confidence among his clientele and has been a natural stimulus of the rise of every shade of cultism.

May not the failure to study pain be responsible for the many forms of physio-psychic therapy which have come and gone during the past half century? Pain in the head, in the back, in the neck, pain in the renal region, pain anywhere, has been considered so casually and superficially that local applications and manipulations have multiplied. Every backache demands attention, and gets it, from all of the manipulators. If the doctor attended to his job and seriously studied spinal deformities, sacro iliac separations, weak feet, broken down feet or flat feet, if he gave to these common every day subjects the earnest study and attention for which he has been prepared by his superior education, would not the ignorant back rubber and spine puncher fade out of the picture?

Physicians who dismiss patients complaining of obscure pain, as neurotics, merely drive them into the arms of people who are more considerate, and very likely into machine shops, presided over by sub-standard practitioners, where buzzing electrical machines are very diverting and quite irresistible. Pain is the chief symptom which urges the subject to seek advice, and he goes for relief and sympathy to anyone who will try to give it.

I know a very busy doctor, you probably do too, who is a buzzing doctor, reminding one of a June bug batting his head against the wall. He does not get very far because he has lost co-ordination. He sees so many patients in an hour that he stops thinking. He descends to superficiality, to the easy morality of following fads. The infectious spirit of the times is largely responsible for such conditions, but the educated physician must change this, he must give every individual who consults him careful, thoughtful consideration. The net result of treating a dozen patients daily with studious thoroughness would be much greater than the net result of handling fifty patients superficially.

We all appreciate the need of re-education, not because of our own material necessity but because of a greater appreciation of the necessity of public health protection. The State Department of Health has been carrying on public health education for many years most actively through food protection, through pasteurization of milk our cities have greatly reduced the incidence of gastro-intestinal infection. Through improved sewer systems, water pollution has been minimized. Through protection of water-sheds, the greatest city in the world has drinking water which is not only the most delightful to sight and taste, but of such purity that it is the safest city water known.

Education in the value of serums and vaccines in preventing the spread of contagious diseases, has been of the greatest value and must be unceasingly continued in the face of the continued opposition of cultists who may be typified by the inclusive term anti-medical.

Recently quoted statistics which related that there were more than 4,000 cases of smallpox here during one month of this year, among our independent citizens, who may or may not, as they please, be vaccinated, as compared with no smallpox in the same month among the 60,000,000 disciplined citizens of Germany, surely make us feel that we are very far from perfection in our public health education or development of public health control.

Health Officers and Public Health Nurses have a wonderful opportunity for broad service. Here would seem an ideal field for young men possessing ample means, and young women with high ideals, to enter upon a real adventure in

had the militia or so-called National Guard, but this force, consisting of some 1,600 companies scattered throughout the United States, was not a federalized military force, and under the constitutional provisions and the lack of congressional laws it was not available as a first-line military force. In 1903 as a result of the passage of the Dick Bill it was recognized as the National Guard, to be organized, equipped and trained like the Regular Army. Provision was made for its participation with the Regular Army in maneuvers, and for the detail of Regular Army instructors and the allotment of federal funds for pay, equipment, and maintenance.

With the exception, therefore, of the militia, this country adhered to its traditional policy of organizing an armed force in time of war, and making practically no provisions for its defense in time of peace.

The present system of Reserves dates from the creation of the Medical Reserve Corps in 1908 when, as a result of the plans prepared by Surgeon General O'Reilly, Congress passed a law authorizing the creation of a Medical Reserve Corps and the appointment of civilian physicians in the corps in the grade of first lieutenants. The Medical Corps of the Army and the medical profession of this country take great pride in the fact that the Medical Reserve Corps was the first officer reserve organization this country ever had. Some of the most prominent medical men of the country enrolled, and one of the first duties performed by those who became reserve officers was the study of preventive inoculation against typhoid, which was first voluntary and later compulsory in the Army.

The development of the Medical Reserve Corps was slow, but the corps which began the war with a membership of 342 in 1917 was increased to 31,000 at the time of the Armistice. The incidents connected with this expansion during the World War are matters of history, depicting the many inequalities, injustices and ineffectiveness which were an inevitable consequence of unpreparedness. No definite methods or standards for appointment, classification, assignment and promotion were in operation, and all of the inequality and discrimination regarding rank and promotion which caused so much bitter feeling during and immediately after the war, are explained entirely by the fact that the medical profession was unprepared for war, and the laws governing appointment and promotion in the Reserves made it impossible to adopt and maintain definite standards and regulations.

The new Reserve Corps began recruitment in January, 1919. Until June of that year there was no law governing the grade upon appoint-

ment. It is a matter of record that appointments during this period were made in the same grade or one grade higher with only four exceptions of record in which officers received more than one grade higher than that which was held while on active duty. From July, 1919, to June, 1920, appointments could be made by law in one grade higher than that held while on active duty. For over a year after the passage of the Act of June 4th, appointments were limited to the same grade, a restriction that was removed by the decision of the Secretary of War in November, 1921. It is believed that the Reserve Corps at the present time is founded on a much firmer basis, and that the regulation governing appointment and promotion having been devised by a board, 50 per cent of whom were reserve officers, will cause no further complaint as to the matter of rank and promotion.

The present Officers Reserve Corps is composed of reserve sections corresponding to each arm and branch represented in the Regular Army, with such additional sections as the President may see fit to create. In the Medical Department we have the Medical, Dental, Veterinary, Medical Administrative Corps, and the Sanitary Corps Sections. There is also an Auxiliary Section to which officers may transfer upon reaching the age of 64, or having become disabled, or who, after having completed 20 years' service, desire such transfer. The Medical Administrative section is composed of officers, not above the grade of Captain, whose qualifications fit them for administrative positions in the Army Medical Department such as those of Adjutant, Mess Officer, Supply Officer, etc. The Sanitary section, which might properly be called the medical auxiliary section, is composed of officers from the grade of second lieutenant to colonel, whose civilian occupations and professions are essential to a well-rounded medical service in time of war. In this class we have sanitary engineers, food and nutrition experts, hospital architects, laboratory technicians, statisticians, and men engaged in the production and procurement of medical supplies on a large scale. These professional and technical officers are required in the Medical Department because in the next mobilization, there will be a more accurate and scientific classification of the men taken into the military service and the salvage of the physically unfit, sick and wounded, and their reconstruction will be carried out on a scale vastly superior to that of any previous war.

Appointments in the Medical Department of the Reserve Corps are made in the lowest grade except World War officers, who may be commissioned in a higher grade, as well as those who, though not having served as offi-

far as we do now into the sciences Hospitals favorably located may have good service from a local supply All hospital patients are more fortunate than are private patients outside of hospitals No one denies the value of the service of the individual nurse, all admit the difficulty of securing her services and large numbers are unable to pay her It does not seem possible that any artificial regulation will sufficiently increase the supply, in proportion to our growth of population, to restore former comfortable conditions Women are in industry to stay and they are going into work that pleases them both in character and reward

Committees from the state and county societies have been studying these questions from various angles and with varying reactions A special committee will continue these investigations and I shall not attempt conclusive deductions from refractory straws which may or may not indicate the direction of uncontrollable social forces

There seems to be general approval of the plans for preventive medicine which involve the examination periodically of the apparently healthy

It seems a natural development from a semi-annual examination of every school child by inspecting physicians and nurses who would weed out defectives, classify them, and follow up their physical care in co-operation with family physicians, pursuing continuous checking up until the age period when they enter industry where the general evolution of economics would bring them under the observation of other health agencies

Standardized health is not only possible but will be insisted upon by employers Annual health inventories will be taken and organized efforts will be made to maintain excellence Much of the preliminary paper work may be done by nurses which will lessen the labor of the examining doctor • Corrective instruction will be given which will be valuable in attaining results In general, the examining physician will himself learn much It is surprising how stimulating careful history taking and a complete estimate of every organ and function becomes with mere performance. The subject also becomes interested

and increasingly respects the examiner as the repository of his personal confidences and of his physical data The family physician is pre-eminently the best qualified to do this work The health officer and the public health nurse could do a real public health service by spreading in formative propaganda

One of the major activities of the Medical Society of the this year will be the inauguration of State-wide post-graduate medical education It is planned to carry this work to the doctor who is too busy to leave his practice for long enough time to take courses in advancing medicine within the walls of educational institutions It is planned to ask the doctor, through the district branches and the county societies, what special form of education he desires, give him what he wants, if possible, and thereby increase the value of his membership in the state society

It may be hoped that Medical Colleges within the State may offer courses to members of the State Society, who, by the fact of their membership, have shown that they are interested in medical progress and therefore deserve special attention from educational institutions

It is also to be desired that the State Department of Health will continue the educational work now being done by regional consultants or others, not only until the State Society is able to do practical work, but also in collaboration upon a general program The field is a large one and there is room for free co-operation of many agencies providing they are willing to avoid duplication of effort

Kipling says

"If you can fill the unforgiving minute  
With sixty seconds worth of distance run,  
Yours is the earth, and, which is more,  
You'll be a man, my son"

If every one of us, physicians and nurses, will, every day, try to practice a little better medicine, a little better surgery and a little better nursing than we did the day before, and do it in the spirit of the commandment, "Thou shalt love thy neighbor as thyself," we will travel far on the road toward the goal of our great adventure

## THE MEDICAL RESERVE CORPS\*

By LT COL CHARLES R. REYNOLDS, M C,

COMMANDANT CARLISLE BARRACKS PENNSYLVANIA

THE Organized Reserves constitute the most important component of the United States Army, the Regular Army and the National Guard, being sufficient only for a minor mobilization From a medical standpoint the Or-

ganized Reserves are necessary as a supplement to complete the military forces, for without the Organized Reserves, there is practically no provision made for the hospitalization and other medical service back of the divisions

For 125 years this country had practically no reserve military force It is true that we

## IN VACATION TIME

While most of our friends seem to be traveling away from here this summer, Colonel Kopetzky, of Medical Week, and Major Overton, of our staff, having deserted their sancta for military manœuvres at Carlisle, and even our Business Manager having yielded, for a very brief period, to the lure of the music of ocean waves, the wheels of the State Society have been turning upon the work cut out for it by the House of Delegates.

The executive committee has held four meetings in order to clear its calendar, and takes pleasure in announcing that the new committee on legislation will be composed of very able and experienced men with Dr. Henry L. K. Shaw as Chairman, and Dr. Arthur W. Booth and Dr. Clarence F. Graham as co-workers.

The special committee on nursing, which is a sub-committee of the Committee on Economics, has organized and started an elaborate program of investigation from which we hope

for a clearer vision of a very difficult problem.

The special committee which was appointed to draft a new medical practice bill holds meetings every two weeks, and every member is giving his very best thought and study in trying to satisfy our critical membership, and construct a bill which will pass the next Legislature.

The Committee on Public Health and Medical Education has organized, will meet again on August 12th, and is working very steadily upon the development of an ambitious program for State-wide post graduate medical education, which is creating a very lively interest among our members. A part of its clinical work has already started, is eagerly received, and warmly applauded.

The President has already spoken before five societies and will disappear into the woods next week to catch his breath for the fall campaign.

N B V E

cers during the World War, contributed to the successful prosecution of the World War in occupations which prohibited their being commissioned in the Army. Among these are the essential teachers, public health officers, and those who served in the Council of National Defense. The deans of medical schools and the professors have been given appropriate rank.

The assignment of Reserve Officers is now made more accurately and scientifically as a result of a careful system of classification made in the Surgeon General's Office wherein the military record and professional qualifications are carefully surveyed to the end that officers may be assigned to the positions they are best qualified to fill. Those who are especially qualified for service with troops are placed in the Territorial Assignment Group, and turned over to the Corps Area Commander for special assignment to units, such as Infantry Divisions. The other large group formally known as the Branch Assignment Group, constitutes more than a majority of all Medical Reserve Officers. From this large group the Surgeon General must organize the medical service back of the divisions including the surgical hospitals and the auxiliary teams, such as shock teams, fracture teams, operating teams, the evacuation hospitals, station hospitals, general hospitals, laboratory units, supply units, and other medical institutions in the Theater of Operations and home territory. Under the new arrangement many of these units will be organized under Corps Area direction.

The promotion of Reserve Officers as well as many other regulations of importance are defined in Army Regulations 140-5, W D, December 15, 1924. The requirements for promotion in time of peace depend upon the length of service in the lower grade, the existence of a vacancy in a higher grade, and the holding of a certificate of capacity which is acquired after a written examination which, with a practical test, will qualify an officer for promotion, provided he meets the general rules as to age and length of service. The service requirement is extremely liberal, providing for the promotion of the officer to the grade of colonel in a period of 16 years. In the Regular Army such promotion requires 26 years of service. The specific regulations as to the requirements for the certificate of capacity and the scope of the written and practical tests for promotion will soon be issued by the War Department. A very important fact which should have a large influence upon building up the Reserve Corps is the security that a Reserve Officer has against interruption of his civil occupation by active duty requirements. The laws and regulations are extremely liberal and in substance provide that active duty is to

all intents and purposes voluntary. Active duty training can be obtained by application to the Corps Area Commander.

The system of training Reserve Officers comprises the Correspondence Courses, active duty in camps of instruction such as the C M T C, active duty with their units under training, and special courses of instruction in the Reserve Officers' camps such as the one held at the Medical Field Service School, Carlisle Barracks, each summer. In addition to these, there is a six weeks' course at Carlisle for National Guard and Reserve Corps Officers beginning September 1st, and an advanced course for the higher training of Regular, National Guard, and Reserve Corps Officers beginning October 15, and ending December 15.

The appointment of Reserve Officers contemplates their specific assignment to units organized under the general mobilization plans of the War Department. In time of a national emergency, it is probable that the Medical Department will be called upon to furnish over 40,000 officers and about 400,000 enlisted men. The organization of the units in which these officers are to serve have gone forward as fast as enrollments and the allotments of the War Department's limited appropriations have permitted. There remain to be formed a great many Medical Department units which will find their activities in the medical service back of the divisions. The plans of the War Department contemplate the organization of all these units locally and their mobilization at their home stations as the first step in the general process of mobilization. The responsibility of Reserve Officers for the organization and mobilization of the units to which they are assigned is readily apparent, and marks a decided departure from the plan in force during the mobilization of 1917.

Why should one join the Reserve Corps? This question is often asked in view of the probability that appointment in the Army of the United States may be obtained after war is declared. The answer is to be based entirely upon the matter of patriotism. Many of the former officers of the Army have declined to accept commissions in the Reserve Corps because of grievances based upon their experience in the Army. The basic cause of the inequalities, injustices, and misfits during the World War was unpreparedness. To lend no aid in the preparation of plans for the effective organization of the resources of the medical and allied professions of the country is to subscribe to unpreparedness and its results during all former wars, which will inevitably cause the same results in the future.

## HONESTY IN MEDICINE

We once wrote an editorial on Medical Honesty in which we emphasized the fact that plain honesty is the fundamental qualification of a doctor (See this Journal, February 1, 1924, page 63) This qualification recurs to us as we read the request of our counsel, Mr Whiteside, for information regarding the causes of malpractice suits brought against doctors (See this Journal, June, 1925, page 799)

We are further reminded of the importance of honesty by requests for advice that are made by members of county medical societies We have unwillingly reached the stage of life when, after twenty years of service as secretary of a county society, the doctors of our acquaintance think that our experience has given us a considerable degree of knowledge about the fine points of the ethics of the relation of one doctor to another, and so our doctor friends unburden their troubles on us in strict confidence

One of the most common complaints is that a second doctor tells a patient that his condition is somewhat different from that which his first doctor has diagnosed One doctor, for

example, makes a conscientious and thorough examination of the lungs and throat of a patient who has bloody expectoration, and he very properly asks the patient to return for a confirmatory examination, and for a sputum specimen The patient goes to a second doctor who makes a superficial examination, and tells the patient what the patient is anxious to hear—that his bleeding comes from his throat

Which doctor will that patient praise?

Which doctor is honest and reliable?

Which doctor practices the Golden Rule?

Which doctor practices modern medicine?

Which doctor would you put on a committee to investigate the causes of diphtheria deaths in your county?

It is thoughtless breaches of strict honesty, such as we have described, that start trouble between doctors, and it is greater breaches of honesty that start most of the malpractice suits against doctors

We would like to start a graduate course of instruction in old-fashioned honesty, but what's the use? Some would say that we would first have to go to school ourself

F O

## QUACKS

Why do quacks flourish? For the same reason that weeds grow Weed seeds are scattered everywhere, but the only ones that grow are those that follow a soil suited to them Quacks spread their alluring propaganda over the whole land, but only here and there does it fall on a public that is so responsive as was a community that we visited recently

It was an old city rich in worldly goods patriotic history and learned culture In its center square a crowd surrounded an automobile in which an accordion player alternated with an orator whose knowledge of practical psychology far exceeded his grammatical learning "See this bottle of muddy liquid?" said he "It contains the poison that makes you sick I pour some into this glass One drop of it would kill you, if it got inside of you Now, watch what this medicine does to it I pour ten drops of this medicine into the glass See how the brown, muddy liquid becomes pure as crystal Look carefully See those particles rising in the liquid? If they sank, they would fall into your bladder and form a stone there Now, who wants the first bottle? Let me warn you—don't you go home and give half of the bottleful to your wife or your mother

If they need any medicine, buy them each a whole bottle Half a bottle will not do any one any good at all Each bottle is exactly fitted to chase the poison from one person Four bottles, did you say? Yes, four dollars is right"

And I saw a young man and his attractive wife take away four bottles of quack stuff as tenderly as they carried their baby, and no one molested the vender save a band of Salvation Army exhorters They took their station beside the quack and sought to drown his voice with a cornet that was out of tune But the dollar bills fell not into the lassie's tambourine but into the hat of the quack

And I asked a friend of mine who was a preacher why the quack was tolerated, and he replied "We have fine doctors here who have great skill, and we all do as they tell us, and the city is healthy But what this man says may be true and, therefore, we buy his medicine, and can you prove to me that what he says is false? We are a people full of faith, and we trust both the doctors and the peddlers of medicine

These things took place in a State where science in general and medicine in particular are on a high plane

F O

## ADVERTISING AND THE JOURNAL

The Publication Committee with the approval of the Executive Committee of the Council has made arrangements with Mr Joseph Tufts to become the advertising manager of this Journal. Mr Tufts has been connected with the Journal for a number of years on part time, but now he will give it his full time with the expectation of greatly increasing the amount of advertising, and therefore the income of the Journal.

The question is often asked "Why does the Journal need to take advertising at all?" The answer is threefold

1 Physicians wish to know where they may get reliable supplies

2 Firms friendly to physicians wish to come into direct contact with their patrons

3 The advertising service is financially helpful to both the advertisers and the Journal

The members of the Medical Society of the State of New York have a great opportunity to bring in new advertising. If they know of firms that would be likely to advertise in the Journal, they can drop a line to Mr Tufts,

who will then follow up the prospective customers

There are many lines of advertising that are now untouched by our Journal. There is the long list of common foods—cereals, canned soups, and ready-to-eat foods whose value would be enormously increased through the recommendation of physicians. There is a long list of toilet articles, from tooth pastes to foot powders, about which physicians are often questioned. There are rain coats, and shirts, and stationery, and automobiles, and there are personally conducted tours for the vacation time of the doctor and his friends and patients. All these may properly be advertised in the Journal.

Reputable advertising firms are willing to pay well for space in the Journal provided they can receive an audience and some return from the advertisements which they will secure subject to the strict censorship of the Publication Committee. We believe that with the cooperation of all our members we can make the Journal far more financially self-supporting without any sacrifice of independence. O S W

## FUNDAMENTALISM IN MEDICINE

Publicity is the greatest weapon in the modern warfare between Truth and Error. H G Wells in his "Outline of History," page 396, tells how the printing press in the time of Rome's greatness would probably have saved the Roman civilization. He says that an efficient popular government depends on a steady supply of correct information upon public affairs to all. This statement is equally true in public health.

Just as the dissemination of knowledge is the principal means of promoting progress, so the suppression of a knowledge of new discoveries in science has always been the means used by the conservatives who object to changes. There is a great class of honest persons who believe that any attack on the "Foundations of the Earth," and on the stability of the "Everlasting Hills," is going to upset the balance of the world and the mentality of its people. These persons have an obsession that research workers are trying to build a tower of science by which they can scale the heights of Heaven.

The recent contest of wits between two self-appointed champions representing the extremes of the two classes of "thinkers" has made exceedingly entertaining reading, and we have envied the reporters whose privilege it was to see the contestants hurl thunder bolts and invectives at each other after the manner of the ancient heroes on the battlefield. (See the

speech of Goliath to David in Chapter 17 of First Samuel.)

There has already been a big sale of scientific books to the fundamentalist rooters. We have not heard that men of science have shown the least disturbance over the charges of agnosticism and atheism that have been brought against them. Physicians and other men of science are exceedingly humble in the presence of the great unknown, and they have a profound faith in Him who rules all things, and in the Book wherein He has revealed Himself. They render unto the Caesars of science the things that belong to science, and unto God the things that are of God. We cannot name a single physician who is an atheist, on the contrary, physicians, more than any other class of persons, honor and revere the minister of the Gospel who walks sincerely in the footsteps of the Master and tries to practice the Sermon on the Mount.

Popguns of oratory and religious polemics have no effect on physicians, whose faith withstands the daily assaults of inconsistency, hypocrisy, and cowardice. These things they soon forget, or they remember them as mere scientific phenomena. The faith of the physician is renewed daily from the great reservoir of faith of those who confess to Him their secret sins, and entrust their very lives to His care. F O

little abduction and rotation. The right trochanter was higher than the left and the clinical findings corresponded with the X-ray, which showed an old fracture of the neck of the femur with the distal part of the neck absorbed and the head very much rarified. The part of the neck attached to the femur appeared to be well nourished. It was also found that the left hip joint was limited in flexion, abduction and rotation, the disability not being as marked as on the right side. Examination of the sacro-iliac revealed no tenderness or other evidence of injury. The lumbar and gluteal muscles on both sides were extremely tender, suggesting myositis. The examining orthopedic physician was of the opinion that the disability of the right hip was due to an old fracture of the femoral neck and that the condition of the left hip was probably due to bone changes consequent upon nutritional disturbances and usually known as osteoarthritis. He was also of the opinion that the fracture of the right

femoral neck antedated the X-ray of April, 1922, anywhere from one to twenty years, the proof of this being the rarefication of the head and the absorption of the distal part of the neck of the femur. He was of the further opinion that he could conceive of no circumstances during delivery which could bring about a fracture of the femoral neck in a woman under thirty years of age or produce an injury to a hip joint which would be followed by osteo-arthritis. He believed that the condition of the lumbar and gluteal muscles is one that usually follows auto-toxemia and could not be produced by traumatism at the time of delivery.

When the case came on for trial the plaintiff's attorney strenuously sought to procure a settlement, being willing to take one hundred dollars for his trouble. When all offers of compromise were refused and we were ready to proceed in behalf of the defendant with the trial of the action, a dismissal of the complaint was consented to.

---

### CLAIMED IMPROPER ADMINISTRATION OF CHLOROFORM AND OPERATION ON CARBUNCLE

The complaint in this action charged that the plaintiff had engaged the defendant as a physician to treat a carbuncle on the right side of her face, that he prescribed a salve, the application of which caused an increase of the inflammation. That he thereafter advised and performed an operation on the carbuncle, under chloroform anæsthesia, which it was claimed was improperly administered, causing the plaintiff to be nauseated, and that the operation was carelessly and unskillfully performed, resulting in an aggravation of the plaintiff's condition and the spread of the infection to the eye, requiring the plaintiff to engage the services of another physician and to be confined to a hospital to undergo further operations and to incur medical and hospital expense, which she sought to recover in this action, together with compensation for the pain and suffering claimed to have been caused by the defendant.

When the defendant was first called to attend the plaintiff for the carbuncle, upon examination he found that the right side of her face was affected with erysipelas which involved the right eye, that her pulse was fast and she had a tem-

perature. He prescribed the application of ichthyol to the carbuncle and gave proper advice with respect to its application. Upon examination of the plaintiff a few days later the carbuncle was in such condition as to require lancing. Under a chloroform anæsthesia administered by a practical nurse under defendant's direction, he made about a two-inch incision in the carbuncle, curetted the wound, cleansed it with a solution of bi-chloride of mercury, and applied a sterile bandage. He remained with the patient until she had come out of the anæsthesia and advised against the consumption of any food that day and to partake of only a liquid diet on the following day. On the day following the operation, when the defendant called on his patient, it was claimed that because of his improper advice she had become nauseated and suffered great pain and another physician had been called in to attend her, thus terminating his services.

The case finally reached its place upon the calendar for trial, and the plaintiff not being ready to proceed with the trial of the action, upon motion the complaint was dismissed, thus favorably terminating the action in favor of the defendant.

# LEGAL

By **GEORGE W. WHITESIDE, Esq.**  
Counsel Medical Society of the State of New York

## CLAIMED DISLOCATION OF FEMUR BY FORCEPS DELIVERY

In this action instituted against an obstetrician, it was charged that by reason of his negligence at the time of delivery of the plaintiff, she suffered a dislocation of the right hip, and a flattened head and shortened neck of the femur. The plaintiff had been under the care of her family physician for her pre-natal condition, and at the time of the commencement of labor she entered the hospital at about 1 o'clock A. M. on the 24th of February, at which time a physical examination was made of her by the house physician. It was found that there was a two-finger dilatation at that time. The patient continued in labor for several days before delivery. The nurse at the hospital who attended plaintiff observed that upon her entrance and prior to delivery she walked with a marked limp of the right leg. On the afternoon of February 26th, no progress having been made by the plaintiff in her delivery, the defendant was called in consultation. He first saw the patient upon the table in the delivery room, where she had been for eight hours. Before the defendant had been called in, the attending physician had advised the performance of a Cæsarean section. The defendant, after his examination of the plaintiff, found that by reason of the delayed labor, the patient was physically exhausted. He also found that the foetal heart was scarcely perceptible, and at that time there was a complete cessation of labor through exhaustion and the foetus was lying very low. From his examination of the plaintiff it was clear that a Cæsarean section was not necessary, but that delivery could be made with low forceps without difficulty. The foetus was lying in a normal position. Upon completion of his examination he advised the husband of the patient of the results of his findings and he was then engaged to deliver the plaintiff. The necessary sterile preparations were then made by the defendant and under a general anæsthesia administered by the hospital anæsthetist, and with the assistance of two nurses and the attending physician, the defendant without difficulty made a low forceps delivery of the plaintiff's child. Prior to his forceps delivery the defendant had been told that the patient complained of pain in one of her legs and hip. He then directed one of the nurses to put into the stirrup only the foot of the leg in which there was no pain, and the leg the patient complained of he directed the nurse to hold in an extended position and not to permit any flexion. At the time of delivery there were no complications

other than a small tear of the perineum which required two or three stitches. A living child was delivered and the placenta expelled intact. Upon completion of delivery the defendant cleansed the patient and applied sterile gauze, and upon inquiry of the anæsthetist was advised that the patient's condition was all right. He then told the attending physician to take care of the after-treatment as his, the defendant's work, was finished, he having been engaged solely for the purpose of delivery. At the time of delivery the attending physician wanted the defendant to permit him to use the forceps in the delivery of the plaintiff, which the defendant refused to permit, stating that he had been engaged for that purpose and it would not be fair or proper to allow the attending physician to use the forceps. The defendant while visiting other patients at the hospital, observed that the attending physician had failed to remove the stitches at the proper time, and he himself removed the same. On March 7th the attending physician ordered the discharge of the plaintiff from the hospital, noting that her condition at that time was O. K. She left the hospital on March 11th.

Several months after the delivery the patient's husband called on the defendant and stated that the patient had difficulty in walking. The defendant then visited the patient's home and procured from her a history that she experienced some difficulty with her hip when a small child, at which time she was operated upon. An examination made of the plaintiff's hip by the defendant disclosed that there was some difficulty and pain when the patient walked. The defendant then referred the patient to an orthopedic surgeon, which was the last time that the plaintiff was seen by the defendant.

The interpretation of an X-ray taken of the plaintiff in April, 1922, by the orthopedic surgeon was "Flat in the head of the femur, with very short niche of femur, with downward dislocation, most likely congenital."

Shortly before the action was about to come on for trial a physical examination by another orthopedic surgeon was had of the plaintiff in behalf of the defendant. On this examination it was found that the plaintiff had a bi-lateral hip limp more marked on the right side, the lower right extremity being about three-quarters of an inch shorter than the left and there being restriction of motion at the hip joint preventing any flexion beyond 110 degrees and allowing very

little abduction and rotation. The right trochanter was higher than the left and the clinical findings corresponded with the X-ray, which showed an old fracture of the neck of the femur with the distal part of the neck absorbed and the head very much rarified. The part of the neck attached to the femur appeared to be well nourished. It was also found that the left hip joint was limited in flexion, abduction and rotation, the disability not being as marked as on the right side. Examination of the sacro-iliac revealed no tenderness or other evidence of injury. The lumbar and gluteal muscles on both sides were extremely tender, suggesting myositis. The examining orthopedic physician was of the opinion that the disability of the right hip was due to an old fracture of the femoral neck and that the condition of the left hip was probably due to bone changes consequent upon nutritional disturbances and usually known as osteoarthritis. He was also of the opinion that the fracture of the right

femoral neck antedated the X-ray of April, 1922, anywhere from one to twenty years, the proof of this being the rarefaction of the head and the absorption of the distal part of the neck of the femur. He was of the further opinion that he could conceive of no circumstances during delivery which could bring about a fracture of the femoral neck in a woman under thirty years of age or produce an injury to a hip joint which would be followed by osteo-arthritis. He believed that the condition of the lumbar and gluteal muscles is one that usually follows auto-toxemia and could not be produced by traumatism at the time of delivery.

When the case came on for trial the plaintiff's attorney strenuously sought to procure a settlement, being willing to take one hundred dollars for his trouble. When all offers of compromise were refused and we were ready to proceed in behalf of the defendant with the trial of the action, a dismissal of the complaint was consented to.

---

#### CLAIMED IMPROPER ADMINISTRATION OF CHLOROFORM AND OPERATION ON CARBUNCLE

The complaint in this action charged that the plaintiff had engaged the defendant as a physician to treat a carbuncle on the right side of her face, that he prescribed a salve, the application of which caused an increase of the inflammation. That he thereafter advised and performed an operation on the carbuncle, under chloroform anæsthesia, which it was claimed was improperly administered, causing the plaintiff to be nauseated, and that the operation was carelessly and unskillfully performed, resulting in an aggravation of the plaintiff's condition and the spread of the infection to the eye, requiring the plaintiff to engage the services of another physician and to be confined to a hospital to undergo further operations and to incur medical and hospital expense, which she sought to recover in this action, together with compensation for the pain and suffering claimed to have been caused by the defendant.

When the defendant was first called to attend the plaintiff for the carbuncle, upon examination he found that the right side of her face was affected with erysipelas which involved the right eye, that her pulse was fast and she had a tem-

perature. He prescribed the application of ichthyol to the carbuncle and gave proper advice with respect to its application. Upon examination of the plaintiff a few days later the carbuncle was in such condition as to require lancing. Under a chloroform anæsthesia administered by a practical nurse under defendant's direction, he made about a two-inch incision in the carbuncle, curetted the wound, cleansed it with a solution of bi-chloride of mercury, and applied a sterile bandage. He remained with the patient until she had come out of the anæsthesia and advised against the consumption of any food that day and to partake of only a liquid diet on the following day. On the day following the operation, when the defendant called on his patient, it was claimed that because of his improper advice she had become nauseated and suffered great pain and another physician had been called in to attend her, thus terminating his services.

The case finally reached its place upon the calendar for trial, and the plaintiff not being ready to proceed with the trial of the action, upon motion the complaint was dismissed, thus favorably terminating the action in favor of the defendant.

# State Department of Health

## HEALTH OFFICERS' CONFERENCE

The Twenty-fourth Annual Conference of the Health Officers of New York State was held on June 23, 24, and 25, in Saratoga Springs, in connection with the Seventh Annual Conference of Public Health Nurses. The sessions, in recent years, have always been held in the Grand Union Hotel, for it is almost the only hotel in the State which can accommodate the thousand or more delegates under one roof. The visitors all ate in the dining room of the hotel, and the meals were three daily social functions.

There are over 900 health officers in the State, most of whom are active members of the Medical Society of the State of New York. We see the same faces in the two organizations, and the Health Officers' Conference is a big factor in promoting the morale of the physicians who are active in the State Medical Society. The records show that 521 health officers registered themselves at the Conference, or over 50 per cent of all the health officers.

The Conference is official, and the Public Health Law makes the attendance of every health officer mandatory at the expense of his municipality.

There are about 1,200 public health nurses in New York State, of whom 308 registered at the Conference. While the payment of their expenses is not compulsory, yet it is to the credit of the employers that they nearly always have paid the expenses of the nurses.

Probably the greatest value of the Conference is in the opportunity for the public health workers of New York State to become acquainted with one another. We have been attending these conferences since their inception in 1902, and we eagerly look forward to the sight of comrades whom we have met every year for a quarter of a century. This annual renewal of friendships promotes unity of purpose, loyalty to the ideals of the State Department of Health, and a fine spirit of service in the cause of public health. The informal sessions (conferences they should be called) in the corridors of the hotel and in the health officers' rooms, and the swapping of stories and experiences, are quite as valuable as listening to addresses from the platform.

This year's conference was of special significance because for the first time the Medical Society of the State of New York was officially recognized on the program. Dr. N. B. Van Etten,

President of the State Society, had a prominent place on the opening program, and both he and Dr. Matthias Nicoll, State Commissioner of Health, emphasized the need of graduate medical education, and each approved the educational plans of the other. The spirit of both addresses was the same, and it was extremely gratifying that each leader should express the identical views of the other without previously consulting together. It augurs well for the future of medicine and of public health that the two great medical organizations of the State should act in close harmony.

We are printing the addresses of both Dr. Nicoll and Dr. Van Etten on pages 859 and 861 of this issue.

A striking feature of the Conference was the spirit of comradeship and democracy in which Drs. Nicoll and Van Etten set the example. The Commissioner of Health spent his time in the corridors where he was one with the health officers. We are sure that every health officer and public health nurse will go home with a new spirit of morale because of the friendliness of the Commissioner. We are sure, too, that the health officers and nurses will have a friendly feeling of co-operation with the State Medical Society because of the opportunity to meet its President on intimate terms during his two-day stay at the Conference.

We had the opportunity to consult health officers from widely separated parts of the State on the subject of graduate education, and found the physicians receptive to the plan of the co-operation of the county societies with the Committee on Public Health and Education of the State Medical Society in planning clinical programs for the meetings, and in arranging graduates' courses of instruction in general medicine, such as heart diseases, tuberculosis, and renal conditions. A large proportion of the health officers of New York State have already taken courses of instruction in their own specialty, and have had experience in making arrangements for lectures and demonstrations. The co-operative attitude of Commissioner Nicoll will be a great factor in the post-graduate education of physicians generally.

This year's official conference of the health officers and public health nurses of New York State marks not one, but several milestones of progress in all that relates to health and the preventive phases of medicine.

F O

# MEDICAL SURVEY

## MEDICAL SURVEY NO 13—SARATOGA COUNTY

Editor's Note—The information on which this Survey is based was supplied principally by Dr J R MacElroy, President of the Medical Society of the County of Saratoga, Dr A R Dimock, Superintendent of the Tuberculosis Hospital of Saratoga County, and Drs George Scott Towne, John B Ledlie, and Carl R. Comstock of Saratoga Springs

**HISTORY**—Saratoga County is one of the best known communities in New York State and the United States, historically, socially, and medically. The physicians of Saratoga County, with those of Montgomery and Washington counties, took the initiative in securing the Medical Practice Act of 1806 under which county medical societies were formed for the purpose of examining and licensing medical students for the practice of medicine, and they were active in the formation of the Medical Society of the State of New York

**POPULATION**—Saratoga County is situated on the west side of the Hudson River, above Albany. It has an area of 823 square miles. Its population was 60,029, according to the census of 1920, and has not increased for twenty years. The distribution of the population was as follows:

The City of Saratoga Springs	13,181
The City of Mechanicsville	8,166
Eight villages	15,100
Strictly rural	23,582
Total	60,029

The people outside of the greater centers are largely prosperous farmers and dairymen.

**PHYSICIANS**—The physicians practicing in Saratoga County are 72 in number, according to the directory of the Medical Society of the State of New York. They are distributed in 15 centers, as follows:

	No of Physicians	Ratio to Population
Saratoga Springs	28	1 to 550
Mechanicsville	9	1 to 900
Ballston Spa	9	1 to 460
Rest of the County	26	1 to 1350
Whole County	72	1 to 830

Saratoga County seems to be well supplied with physicians, even in its rural section. But the directory contains the names of at least a dozen physicians who are no longer practicing medicine. Deducting these, there are left 60 physicians in active practice. This makes a proportion of one doctor to every 1,000 of population.

**COUNTY MEDICAL SOCIETY**—The Medical So-

ciety of the County of Saratoga has 51 members, or 70 per cent of the physicians listed in the directory. This proportion is about the same as that for the whole state. If only the active physicians are considered, 83 per cent belong to the County Society—a high percentage.

The Society holds two meetings annually. While the programs of its meetings are almost entirely scientific, yet the Society has practiced excellent civic medicine along three lines:

1 It has been the means of securing a County Laboratory.

2 It has established a system of certifying milk.

3 It has sponsored a series of lectures for the physicians of the County.

The County Medical Society has a milk commission composed of Drs Towne and Comstock. They have formulated rules and regulations regarding the production of certified milk in Saratoga County. The County Society, through its President, Dr MacElroy, also secured an appropriation from the Board of Supervisors for the purpose of testing dairy heads for tuberculosis.

The lecture series was planned and conducted by Dr J R MacElroy, President of the Society, who secured speakers from Albany, Schenectady, and other medical centers. Thirteen lectures in all were given during 1924, with an average attendance of about a dozen physicians. Some of the subjects of the lectures were: The Causes of Prolonged Labor, Diabetes, Pneumonia, the Differential Diagnosis of Surgical Conditions of the Abdomen, the Nervous Child, Non-Tuberculous Diseases of the Chest, Acute Infections of the Nasopharynx, Non-Surgical Diseases of the Abdomen, and Fractures.

These lectures are along the lines which will be promoted by the Medical Society of the State of New York during the present year, and the physicians of Saratoga County are true to the traditions of their predecessors who, a century and a quarter ago, took the lead in a movement which became state-wide, and resulted in the formation of the Medical Society of the State of New York.

Dr H J Hawk, Superintendent of the Mount McGregor Sanatorium, has frequently arranged lectures on medical subjects in his institution, and has invited the physicians from the surrounding counties to them. An attendance of 100 has been common, and physicians have come from Albany, Troy, Glens

Falls, and Schenectady, to hear the lectures

Graduate Medical Education has been well started in Saratoga County by the spontaneous impulse of its own physicians

The Medical Society of the City of Saratoga Springs is composed of about 30 physicians who practice in the city and its vicinity. It meets on one evening in each month, and holds a scientific session followed by a social supper. Its attendance averages twenty-five. It is a great factor in promoting the practice of scientific medicine by its members.

Hospitals. Saratoga County has three hospitals for the care of its own sick, as follows:

1. The Saratoga Hospital, in Saratoga Springs, with 100 beds.

2. The County Tuberculosis Sanatorium, at Middle Grove, with 50 beds.

3. The McCarthy Hospital, with 20 beds.

The county has 170 hospital beds available, or 2.8 beds for every 1,000 of population. This is a rather low proportion.

The Saratoga Hospital is housed in a well-planned, roomy brick building which at present prices would cost \$400,000. It receives all kinds of general medical and surgical cases. It is an open hospital, but conforms to the standards of the American College of Surgeons. Staff meetings are held monthly which are attended by over fifty per cent of the physicians listed on the staff—a high percentage for an open hospital.

The histories of the cases are well kept, but much credit for their high standard belongs to the history clerk, who takes the physicians' dictations on call. Another factor in promoting their good histories is the rule that no patient can be discharged unless the history is complete—and the rule works.

The County Laboratory is located in the hospital, and three technicians are employed. The laboratory and hospital also have the services of the experts from the research laboratory at Mt. McGregor on call.

The hospital has the use of an extensive X-ray equipment which belongs to Dr. E. H. King of the Staff, who gives free services to poor patients in the wards.

A training school is maintained with 33 pupil nurses, and a staff of 6 graduate nurses.

**Tuberculosis Work.** The County Tuberculosis Sanatorium has a capacity of 50 cases, but it is nearly always over-filled, and always has a waiting list. Tuberculosis clinics are held frequently in several parts of the County by the Superintendent, Dr. A. R. Dimock. Two public health nurses are employed to do field work in tuberculosis.

Saratoga County has appropriated \$3,000 for a camp for about 30 tuberculous children. This sum is duplicated by the State of New York.

The County has a lay Tuberculosis Com-

mittee which raises about \$3,000 annually by the sale of Christmas Seals, and gives the money toward the support of a field nurse.

The physicians of Saratoga County are well disposed toward the tuberculosis work, and give loyal support to the field nurses and the Superintendent of the Sanatorium.

**Public Health Work.** The official public health work of Saratoga County is carried on by 20 health officers who serve 25 cities, 8 villages, and 19 rural districts. Each health officer of a rural district serves an average of 2,200 population. About three-quarters of the health officers have taken a special course of instruction conducted by Dr. C. C. Duryee for the State Department of Health.

A public health laboratory was established by the Supervisors of the County in Saratoga Hospital, and every physician in the County has patronized it during the past year—a gratifying record.

**Mount McGregor Sanatorium.** The Sanatorium conducted by the Metropolitan Life Insurance Company at Mount McGregor has an excellent influence on medicine in Saratoga County. This Sanatorium is a model of its kind, both in equipment and the manner of carrying on its work. About half of the cases are tuberculous, and the rest are of general diseases, such as cardiac, renal, and diabetic. A Research Laboratory is maintained at which excellent original work is done. One piece of work was the demonstration that tubercle bacilli could be excreted continuously by the urine of tuberculous animals through microscopic foci in kidneys which appear normal on gross examination. The results of this research are published in the American Review of Tuberculosis for January, 1925.

The members of the Hospital Staff are on friendly terms with the physicians of the County. They take an active part in all local medical activities, and invite the local physicians to lectures and conferences at the Hospital, and the invitations are eagerly accepted.

**Mineral Waters.** When Saratoga is mentioned, the mineral springs come to mind. But the mineral waters are no longer the dominating factor in the prosperity of the County, and the private sanatoriums are now devoted to other uses. One of the largest is now a dormitory for the students of Skidmore College.

**Impressions.** The physicians of Saratoga County are going about their work modestly and quietly. When they have measured themselves by their own yardsticks, they have given themselves low marks, but when we have measured their activities and aspirations by state-wide standards, we are inclined to give them an honorable rating. F. O.

# GRADUATE EDUCATION

## THE COMMITTEE ON PUBLIC HEALTH AND EDUCATION

The Committee on Public Health and Medical Education is preparing its program. Plainly charged with a definite responsibility to the public and the profession, it sees in the continuous education of the practicing physician the greatest possible contribution to the cause of public health. It will, then, emphasize graduate education.

We do not expect to train specialists, nor, for the present at least, do we plan comprehensive courses in the laboratory sciences. We do, however, hope to reach every doctor in the State, and to do our best to solve for him the common ordinary problems of the everyday practice of medicine. We will create opportunity.

There have been gaps in the education of all of us. The curriculum of the school from which we graduated was by no means perfect, nor is it now. Our internship was what we made it. Experience has been our best teacher. We have learned by observation, and by giving careful thought to the problems which beset us. We are, in a sense, self-taught. There is much that we do not know.

We have done our best. Our morale has always been high. Medical societies, journals and books, hospitals and an occasional post-graduate course have all helped us to keep the faith. We were always ready to give our best.

It may, perhaps, be trite to say that medicine is an art as well as a science, and that the majority of diseased conditions yield to clinical methods. Bedside healing, however, calls for science as well as art, and many problems may be solved by adequate knowledge and the proper evaluation of modern methods of inquiry.

It may be said that this is self-evident, and that graduate education needs no defense. This may or may not be true, but New York State at any rate, we feel, is ready.

The House of Delegates, at its 1924 meeting, authorized a special committee to study the problem. It renewed the authorization in 1925, and recommended "That the promotion of graduate medical education be one of the major activities of the State Medical Society during the coming year. The need and desire for graduate medical education exists, and it only awaits practical organization of method. In these times of rapid change of knowledge and practice, there is need for some method of providing a steady stream of medical information to all sections away from medical centers, as well as to make available to city practitioners the results of medical progress. This work belongs to organized medicine."

The practical difficulties are enormous, and the Committee will welcome help from every quarter of the State. The work is new, and the Committee is spending much time in organization. Made up with a definite idea as to geographical distribution, knowledge of the problem, and ability and willingness to devote much time to the service of the State, the Committee on Public Health and Medical Education is

Dr Charles A. Gordon, Brooklyn, Chairman  
Dr George F. Chandler, Kingston  
Dr Louis A. Friedman, Bronx  
Dr Frank D. Jennings, Brooklyn  
Dr William D. Johnson, Batavia  
Dr Robert S. Macdonald, Plattsburgh  
Dr Edwin MacD. Stanton, Schenectady  
Dr Martin B. Tinker, Ithaca  
Dr Herman G. Weiskotten, Syracuse

The special Committee on Graduate Instruction authorized by the House of Delegates and appointed by the President, consists of

Dr Charles A. Gordon, Brooklyn, Chairman  
Dr Stanhope Bayne-Jones, Rochester  
Dr Andrew MacFarlane, Albany  
Dr Grant C. Madill, Ogdensburg  
Dr Grover C. Wende, Buffalo

There will be no overlapping of function or effort. Both committees have the same chairman, and joint action in the field of graduate education will be carried on.

The Presidents of the District Branches have been constituted an Advisory Council, and as time goes on, they will become increasingly useful in that capacity. The Committee is surveying the State along the geographic lines of the District Branches, much time and effort will be given to a careful study of the field before any complete plan of action can be announced. The problem, however, will not wait upon the time of the survey, so it is the intention of the Committee to begin courses of instruction at once among those groups that are prepared for it, or very anxious to receive it. Courses which the Committee approve had been given in six counties—Jefferson, Kings, Saratoga, Steuben, St. Lawrence and Suffolk—before this Joint Committee of the State had been formed, and a clinical course is now being conducted in Orange County under the auspices of the Committee.

We are considering clinical courses, demonstrations, and graduate education by mail, but a comprehensive program can only develop when district branches, county societies and their officers, and every doctor in the State interests himself in

what we are trying to do, and offers his assistance. Progress will come. The Committee hopes that county societies will look to it for assistance, as we are ready to provide clinical programs at once for those that desire them. We will secure and assign teachers at once for those groups who will agree to provide cases for demonstration when required, and have histories, physical examinations and other data written up and available for the lecture. Only in this way can any real good come from the teaching material used.

The State Department of Health has placed at our command its entire list of Regional Consultants in Pediatrics and Obstetrics. This is our most important ready asset.

The Tuberculosis Committees—National, State and County—are organized to aid in health and education, and the staffs of the tuberculosis hospitals are available for clinics and demonstrations. The latest knowledge in the recognition and treatment of tuberculosis could be easily brought within the reach of every physician, as is done now in Suffolk County under the direct auspices of the County Medical Society.

The members of the staffs of the State hospitals for the insane and the mental defectives are available for teaching purposes, for they are most anxious to lend their aid in stressing the importance of early treatment. In the Utica State Hospital one-fifth of the cases have entered the institution of their own accord as a result of clinics conducted in various cities by the staff of the hospital. (See this Journal, August, 1924, page 813.)

Possibly there are many lay health organizations which may be found willing to co-operate with the Medical Society of the State of New York, their special interests can best be advanced through the ranks of the medical profession itself.

This rather superficial outline of the hopes and thoughts of the Joint Committee is submitted to the members of the Medical Society of the State of New York as a partial account of our stewardship. We are ready to give service at once. More later. We hope to stimulate thought and suggestions. We invite correspondence.

CHARLES A. GORDON, *Chairman*,

## A COURSE IN OBSTETRICS

The Medical Societies of the Counties of Jefferson and St. Lawrence have arranged and conducted a valuable course in obstetrics through the initiative of Dr. Page E. Thornhill of Watertown. Dr. Thornhill is Regional Consultant in Obstetrics for the State Department of Health, and after consulting with Dr. S. W. Sayer, District State Health Officer, a course of six lectures and demonstrations was planned under the auspices of the State Department of Health, which met the necessary expenses. After the plan was developed, it was presented to the leaders of the Medical Societies of Jefferson and St. Lawrence Counties, and on their approval the following letter was sent to every member of both societies:

"In an effort to keep abreast with progress in Obstetrics when there is no opportunity locally for post-graduate study, the undersigned physicians express interest in the short lecture and demonstration course in this subject proposed for Watertown. If there can be arranged a course of lectures, to be given during the early spring months by obstetricians from the teaching centers, we promise our regular attendance.

"It is understood that, through the courtesy of the Division of Maternity and Child Hygiene, no expense is attached."

Signed

Nearly all the doctors in both counties signed the note and showed their earnestness by attending the lectures, some driving 35 miles.

The course consisted of six lectures, one a week, beginning April 16, 1925. As finally carried out, the schedule was as follows:

1 April 16—Prenatal Care. Dr. J. O. Polak, F.A.C.S., Professor of Obstetrics and Gynecology, Long Island College Hospital, Brooklyn.

2 April 23—Management of Normal Labor. Dr. J. K. Quigley, F.A.C.S., Obstetrician, Rochester General Hospital, Rochester, N. Y.

3 April 30—Post-Partum Care. Dr. Harold Bailey, F.A.C.S., Associate Professor in Obstetrics and Gynecology, Cornell University Medical College, New York City.

4 May 7—Pathology of Pregnancy (1). Dr. Polak.

5 May 21—Pathology of Pregnancy (2). Dr. Francis Goldsborough, F.A.C.S., Professor of Obstetrics and Associate Professor of Gynecology, University of Buffalo, Department of Medicine, Buffalo, N. Y.

6 June 4—Pathology of Labor. Dr. Bailey.

Each lecturer gave his talk and demonstration twice—in the afternoon at Ogdensburg to the St. Lawrence County doctors, and in the evening to the Jefferson County men. Some doctors from Lewis County also attended. Each Watertown lecture was preceded by a social supper, when the lecturers formed the acquaintance with the doctors. The local physicians supplied cases for clinical demonstrations whenever the subject permitted.

The average attendance at each lecture was about forty-five. The lectures were simple and practical, and dealt with common points of everyday practice. They afforded a striking demonstration of the eagerness of the physicians to hear up-to-date descriptions of modern methods in obstetrics. They are a model which other county

societies may follow with a certainty of success.

Similar courses in other counties may be arranged through Dr C A Gordon, Chairman of the Committee on Public Health and Education of the Medical Society of the State of New York.

F O

## HEALTH OFFICERS' COURSE IN JEFFERSON AND ST LAWRENCE COUNTIES

An extensive course in all phases of modern public health work has recently been completed at Watertown for the benefit of the health officers of Jefferson and St Lawrence Counties. The course was arranged by Dr F W Sears of Syracuse, assisted by Drs S W Sayer, Gouverneur, and C H Hervey, Oswego, all District State Health Officers. Twenty-three health officers enrolled for the course, as follows: Dr John T Fowkes, LaForgeville, Dr John T Fowkes, Jr, Clayton, Dr Elmer E Eddy, Redwood, Dr S C Hollis, Adams, Dr Byron Haskin, Theresa, Dr Oliver J LaFontaine, Chaumont, Dr Charles C K. Phelps, Sacketts Harbor, Dr F Edward Jones, Beaver Falls, Dr Cyrus J Severance, Mannsville, Dr Willard S Perrigo, Antwerp, Dr M D Barnette, Watertown, Dr Stanley W Sayer, Gouverneur, Dr David M Mills, Gouverneur, Dr William H Cramer, Copenhagen, Dr C W Bullard, Black River, Dr T A Lewis, Hammond, Dr G S Farmer, Watertown, Dr R F Gates, Brownville, Dr M M Ryan, Philadelphia, and Dr Frank Loomis, Watertown.

The attendance was over 95 per cent. A fee of \$25 was charged to cover necessary expenses.

The course was held on two mornings of each week, beginning April 14, 1925. Nineteen sessions were held in Watertown, and one in the

State Hospital in Ogdensburg. The class met one week at Syracuse during the meeting of the State Medical Society, and another week in Saratoga Springs at the Annual Conference of Health Officers.

Thirty-one lecturers composed the teaching staff. The subjects included bacteriology, serology, epidemiology, tuberculosis, sewage disposal, mental hygiene, milk and water supplies, goiter, pediatrics, public health administration, school inspection, and medical publicity. The subjects were treated from the standpoint of the physician rather than that of the official health officer.

At the close of the last session the doctors said among themselves: "Now this course has showed us how to do better practice of medicine. Let us show our appreciation to Dr Sears in a tangible way"—and they did by buying him a fine traveling bag.

This is the twentieth course that has been conducted by Dr Sears during the eleven years that he has been connected with the State Department of Health, and over 200 physicians have been under his instruction. The importance of the courses is increased by the fact that about one in every six doctors up-State are health officers, and most of them have taken a course of instruction.

F O

## HEALTH OFFICERS' COURSE IN ALBANY

A Course for the Health Officers in the vicinity of Albany has been directed by Dr Charles C Duryee, Consultant in City Health administration, State Department of Health. It was given under the joint auspices of the State Department of Health and the Albany Medical College. The course began on March 5, 1925 and was held every Thursday until June 18th, with nine extra sessions, making twenty-five days of teaching. The sessions were concluded on June 19th with a dinner at the Ten Eyck Hotel, Albany. Forty-one instructors were listed on the teaching staff, and sixty-one lectures, clinics and demonstrations were given, covering every phase of public health work. The subjects were those which every physician must meet in his daily work, and attendance on the course will make any doctor a better practitioner of medicine.

This is the seventh annual course that has been directed by Dr Duryee, and 175 doctors have

graduated under him. The present class numbered twenty-two, as follows: Dr Charles Bailey, Hudson Falls, Dr Walter S Bennett, Granville, Dr Ray D Champlin, Oneonta, Dr Wm Burgess Cornell, Albany, Dr J C E Daunais, Cohoes, Dr Lyman Driesbach, Middleburgh, Dr James M Dunn, Schenectady, Dr Samuel H Hodgson, Stuyvesant, Dr C D Hulbert, Westerlo, Dr Leonard A Hulsbosch, Fort Edward, Dr James F Johnston, Albany, Dr William R Lee, North Creek, Dr Wilbur F MacDonald, Corinth, Dr Thomas Leo Mahony, Poughkeepsie, Dr Alexander F Mosher, South Glens Falls, Dr William L Munson, Granville, Dr Louis A Parmenter, Corinth, Dr Chas A Prescott, Hudson Falls, Dr Bertrand E Roberts, Albany, Dr Benj W Stearns, Unadilla, Dr W U Taylor, Mooers, Dr Melvin T Woodhead, Amsterdam.

F O

what we are trying to do, and offers his assistance. Progress will come. The Committee hopes that county societies will look to it for assistance, as we are ready to provide clinical programs at once for those that desire them. We will secure and assign teachers at once for those groups who will agree to provide cases for demonstration when required, and have histories, physical examinations and other data written up and available for the lecture. Only in this way can any real good come from the teaching material used.

The State Department of Health has placed at our command its entire list of Regional Consultants in Pediatrics and Obstetrics. This is our most important ready asset.

The Tuberculosis Committees—National, State and County—are organized to aid in health and education, and the staffs of the tuberculosis hospitals are available for clinics and demonstrations. The latest knowledge in the recognition and treatment of tuberculosis could be easily brought within the reach of every physician, as is done now in Suffolk County under the direct auspices of the County Medical Society.

The members of the staffs of the State hospitals for the insane and the mental defectives are available for teaching purposes, for they are most anxious to lend their aid in stressing the importance of early treatment. In the Utica State Hospital one-fifth of the cases have entered the institution of their own accord as a result of clinics conducted in various cities by the staff of the hospital. (See this Journal, August, 1924, page 813.)

Possibly there are many lay health organizations which may be found willing to co-operate with the Medical Society of the State of New York, their special interests can best be advanced through the ranks of the medical profession itself.

This rather superficial outline of the hopes and thoughts of the Joint Committee is submitted to the members of the Medical Society of the State of New York as a partial account of our stewardship. We are ready to give service at once. More later. We hope to stimulate thought and suggestions. We invite correspondence.

CHARLES A. GORDON, *Chairman*,

### A COURSE IN OBSTETRICS

The Medical Societies of the Counties of Jefferson and St. Lawrence have arranged and conducted a valuable course in obstetrics through the initiative of Dr. Page E. Thornhill of Watertown. Dr. Thornhill is Regional Consultant in Obstetrics for the State Department of Health, and after consulting with Dr. S. W. Sayer, District State Health Officer, a course of six lectures and demonstrations was planned under the auspices of the State Department of Health, which met the necessary expenses. After the plan was developed, it was presented to the leaders of the Medical Societies of Jefferson and St. Lawrence Counties, and on their approval the following letter was sent to every member of both societies:

"In an effort to keep abreast with progress in Obstetrics when there is no opportunity locally for post-graduate study, the undersigned physicians express interest in the short lecture and demonstration course in this subject proposed for Watertown. If there can be arranged a course of lectures, to be given during the early spring months by obstetricians from the teaching centers, we promise our regular attendance.

"It is understood that, through the courtesy of the Division of Maternity and Child Hygiene, no expense is attached."

Signed

Nearly all the doctors in both counties signed the note and showed their earnestness by attending the lectures, some driving 35 miles

The course consisted of six lectures, one a week, beginning April 16, 1925. As finally carried out, the schedule was as follows:

1 April 16—Prenatal Care. Dr. J. O. Polak, F.A.C.S., Professor of Obstetrics and Gynecology, Long Island College Hospital, Brooklyn.

2 April 23—Management of Normal Labor. Dr. J. K. Quigley, F.A.C.S., Obstetrician, Rochester General Hospital, Rochester, N. Y.

3 April 30—Post-Partum Care. Dr. Harold Bailey, F.A.C.S., Associate Professor in Obstetrics and Gynecology, Cornell University Medical College, New York City.

4 May 7—Pathology of Pregnancy (1). Dr. Polak.

5 May 21—Pathology of Pregnancy (2). Dr. Francis Goldsborough, F.A.C.S., Professor of Obstetrics and Associate Professor of Gynecology, University of Buffalo, Department of Medicine, Buffalo, N. Y.

6 June 4—Pathology of Labor. Dr. Bailey.

Each lecturer gave his talk and demonstration twice—in the afternoon at Ogdensburg to the St. Lawrence County doctors, and in the evening to the Jefferson County men. Some doctors from Lewis County also attended. Each Watertown lecture was preceded by a social supper, when the lecturers formed the acquaintance with the doctors. The local physicians supplied cases for clinical demonstrations whenever the subject permitted.

## TUBERCULOSIS TEACHING IN SUFFOLK COUNTY

The first class in tuberculosis authorized by the Suffolk County Medical Society has held a two-hour session on every Wednesday afternoon of July in the Suffolk County Tuberculosis Sanatorium under the leadership of Dr E P Kolb, Superintendent of the Institution. The attendance has averaged six, which is the size of the classes that were originally planned. The subjects discussed at the classes have been as follows:

1 Historical—Types, Channels of Infection and Modes of Onset

2 Symptoms and Signs of Incipient Tuberculosis

3 Tuberculosis in Children—Incipient and Advanced

4 Common Complications of Tuberculosis—Laryngeal, Bone, Joint and Abdominal

5 Chronic Non-Tuberculosis Infections of the Lungs, Bronchiectasis, Emphysema, Bronchitis, Lung Abscess, etc

Clinical cases were shown at each lecture, and the modes of treatment were demonstrated.

Another class will be started in September, and the series will be continued until every physician in the County has had an opportunity to learn tuberculosis. Dr Kolb's course has a significance that is more than local. It is a careful laboratory experiment and demonstration of how to teach tuberculosis to average family doctors, simply, clearly, and attractively. F O

---

## SARATOGA COUNTY MEDICAL SOCIETY

A regular meeting of the Saratoga County Medical Society was held at Newman's Lake House, Saratoga Springs, on Tuesday, June 30th, 1925, with 27 members present and the President, Dr J R MacElroy, presiding.

The subject of Graduate Education was discussed at some length, and Dr J S Lawrence, Executive Officer of the State Medical Society, outlined the plans of the State Medical Society. The project was well received by the members, and the meeting appointed Dr Thomas Goodfellow, Saratoga Springs, Dr E J Callahan, Schuylerville, and Dr J R MacElroy, Jonesville, a committee to arrange clinical lectures and courses in instruction in cooperation with the State Society. It was decided to send a questionnaire to all the members of the County Society in order to ascertain their preferences as to subjects. It is

planned to begin a course of instruction about the first of October.

A committee on public health was appointed, consisting of Dr G S Towne, Saratoga Springs, Dr L A Parmenter, Corinth, and Dr William Van Doren, Mechanicsville.

A committee on medical economics was also appointed consisting of Drs Earl King and Miles Varney of Saratoga Springs, and Dr C J Higley, Ballston Spa.

The scientific program consisted of two numbers.

1 Bradley P Kirschberg, Ph G, Dean of the Schenectady Police School, described some of the newer toxicological problems.

2 Dr Ellis Kellert, Pathologist of the Ellis Hospital Laboratory, at Schenectady, spoke on the subject Differential Diagnosis between some Chemical and Bacterial Poisonings.

## CLINICAL MEETING, ORANGE COUNTY MEDICAL SOCIETY

The third monthly Clinical Meeting of the Orange County Medical Society, in co-operation with the Medical Society of the State of New York, was held on July 21st, in the Sullivan Street School House, in Port Jervis, with twenty-three doctors present. Dr. N. B. Van Etten, President of the Medical Society of the State of New York, was also present and received the familiar greetings of many of the doctors who knew him when his father practiced medicine in the city. Dr. Van Etten gave a ten-minute address on the service which the State Society can render to the local physicians. He emphasized the importance of closer affiliation with the State Medical Society and of Fellowship in the American Medical Association, the necessity of one hundred per cent membership in the Group Insurance plan of the State Society, and the value to all physicians of co-operation in the post-graduate medical education plan of the State Medical Society.

The scientific part of the meeting consisted of a clinic on general Pediatrics by Dr. Charles Hendee Smith, Clinical Professor of Diseases of Children in the College of Physicians and Surgeons, New York, and Director Children's Division, Bellevue Hospital, New York. He demonstrated his points upon cases which were brought to the meeting place by the physicians of the city about an hour previous to the clinic in order that they might be examined and classified without loss of time during the clinic.

The first three children were cases of mental deficiency, all due to mongolism of different degrees. The mental condition of these children was entirely the result of their physical state. They are often the last of several children or the first of a very young mother. Dr. Smith brought out the necessity of an accurate diagnosis in these cases. They are often mistaken for cretins, but thyroid and other glandular extracts are useless as is also any other form of medication. Special mental training helps the milder cases to some extent.

The next case was one of acute stomatitis which Dr. Smith said was infectious, and self limited. It was best treated with mild, soothing applications, and food which is not sweet, salt or sour, i. e., cereals and diluted milk. Its interest

is largely in the diagnosis, since it is often not appreciated that an inflammation of the mouth may be the cause of a fever. These children are often very sick.

The fifth case was a nine-months-old baby, poorly nourished. It was the only survivor of five children. Two former children had died from what was diagnosed as chronic diphtheria because of a persistent reddish discharge from their noses. This one also has a nasal discharge and general enlargement of the superficial lymph nodes.

The diagnosis was plainly lues, but a blood specimen of the parents had been reported negative, although the father has a perforated nasal septum.

Although the child needs a correct diet, treatment of the lues was also necessary before it would improve.

The next two cases had rickets in rather severe forms. Both were pale and white, and neither had been exposed to direct sunlight, although they were put out of doors every day "to get the air" on a porch under the trees.

Dr. Smith gave an interesting talk on the importance of sunlight in the prevention of rickets, and said that the exposure of the face, hands and feet to the direct sunlight for part of every day, would almost surely prevent a child from developing rickets, but the exposure must be to the direct sun and not through glass.

The last case was a child four years old, who was thin and weak, had no appetite, and could not be made to eat. Dr. Smith said that these children were in a chronic state of fatigue, and that the first essential was to treat the fatigue. The treatment outlined was that the child should be put to bed and kept there with its toys and playthings. The proper food should be brought to the child's bed without comment, and in half an hour should be removed, still without comment. The child will eat as it gets over its fatigue, and will get up and continue to eat when it is fully rested.

The series of clinics will be continued as a demonstration of the co-operation between the county societies and the State Medical Society through its Committee on Public Health and Education.

F O

tific Programs?—Dr G J Curry, of Flint, Secretary of the Genesee County Medical Society

4 Aids in Secretarial Work—Dr H L French, of Lansing, Secretary of the Ingham County Medical Society

5 Community Responsibility and the Work of the County Society—Dr D F Kudner, of Jackson, Secretary of the Jackson County Medical Society

6 Co-operation With County Medical Societies—Mr H G Smith, Executive Secretary of the State Medical Society

7 Round Table Discussions—Conducted by Dr Warnshuis

Each subject was presented briefly and concisely, and within five minutes, and then followed a general discussion. The topics centered around the specific major activities which are promoted by the State Medical Society. The talks might be divided into three groups of subjects

1 Inspirational, and the statement of fundamental ideals

2 The broad activities of the State Medical Society

3 The details of the execution of the plans by the State and County Medical Societies

Dr Warnshuis stated the four fundamental ideals of a County Medical Society to be

1 To enlist and interest all the eligible members of the profession in your county in the work of your County Society

2 To cause your Society to enhance the type of medical service in your community

3 To re-awaken the spirit of organized effort for the attainment of the mastery and honor of our profession

4 To beget professional fellowship

These are specific understandable ideals, and for the purpose of attaining them, Dr Warnshuis makes four specific suggestions which are the major activities of the State Society. These suggestions are as follows

1 Bring about better scientific programs for your regular meetings

2 Foster, inspire, and institute with the aid of selected members, an increasing number of public meetings for the education of the public in regard to scientific medicine

3 Adopt and develop a plan of periodic physical examinations

4 Join with and assume directing control of all public health work, clinics and hospitals in so far as medicine is involved. (This last suggestion embraces what we have called the practice of Civic Medicine—The Editor)

A study of the minutes of the Secretaries' Conference gave us the impression that the four

major means for carrying out the activities of the State Society were

1 The Journal of the Michigan State Medical Society

2 The field work of the Executive Secretary

3 The Joint Committee on Public Health Education

4 District conferences

The Joint Committee on Public Health Education was formed in 1922 on the initiative of the Michigan State Medical Society. The organizations which were represented on the Committee are the State Medical Society, the University of Michigan, the Detroit College of Medicine and Surgery, the State Department of Health, the State Dental Society, the Michigan Tuberculosis Association, the State Nurses' Association, the State Conference of Social Work, and the Wayne County (Detroit) Committee on Education

The object of the Joint Committee is to supply popular lectures on medical topics to lay organizations. The Committee has about 200 speakers listed. During the past year, the Committee arranged for 271 lectures, at which the average attendance was 289 persons

At least nine district conferences have been held. The May Journal, page 268, and the June Journal, page 330, carry brief accounts of two conferences which are called Post Graduate Conferences. The programs consisted of all day scientific and clinical sessions, broken at noon by a luncheon by a Rotary or other civic club, and an evening popular session under the auspices of a civic organization, such as a Parent-Teacher's Association. The account in the June Journal concludes

"The ninth Post-Graduate Conference has brought more proof to the fact that Post Graduate Conferences that are conducted by the State Society in co-operation with councilor districts, and County Societies are what the members of these Societies desire"

When we analyze the suggestions made by the county secretaries, we find a wealth of details

Regarding programs, we note the following plans which have been used

1 Teams of members to arrange programs

2 Exchange of speakers with other Societies, or one Society to put on a program for a neighboring Society

3 Clinical programs like those of a staff meeting of a hospital

4 Social activities—lunches and picnics

As aids to secretarial work we note

1 Getting committees to do the details of the secretary's work

2 Clerical assistance to attend to mailing and filing

# OUR NEIGHBORS

## STATE MEDICAL JOURNALS

Anyone who wishes to be broad minded, up to date, and efficient, must know what other people are doing in his line of work. We have had our hands full doing the necessary work that belongs to the editorial office, but now that the summer season has come when doctors prefer fishing to reading, we have an opportunity to study what our neighbors have to say about themselves.

There are thirty-one medical publications which are the organs of forty-one state medical societies. There are only seven state medical societies that have no published organs. We receive the *State Journals* through our exchange list, and have set ourselves to the pleasant task of interpreting the civic activities of the leaders of the several State Medical Societies as they are revealed in the *Journals*.

We are aware of the modesty of physicians generally, and realize that they usually do much more than they tell about. Yet their practice of civic medicine is done by groups as the doctors are associated in county, state, and national societies. We are especially interested in the work of medical groups, and in what they are doing both for themselves and also for the people generally. We can get this information from the statements of the objectives and ideals of the leaders as told in their society meetings, and from the records of their achievements as shown by their reports.

We are beginning what we hope will be a permanent feature of this *Journal* as we review the work of the Michigan State Medical Society, and give our impressions of the publication of a county medical society in Pennsylvania. F O

## THE CONFERENCE OF SECRETARIES OF THE COUNTY MEDICAL SOCIETIES OF MICHIGAN

The *Journal* of the Michigan State Medical Society is the official organ of the State Society and of its 56 constituent county societies. The present membership of the State Society is about 3,000 out of 4,500 physicians in the State. The form of organization of the State Society is almost exactly like that of the Medical Society of the State of New York. There are the House of Delegates, the Council, the Executive Committee, and the Executive Officer who, however, is a layman in Michigan.

The *Journal* is in reality the organ of the State Medical Society, and records and reflects its activities. Its editor is Dr. F. C. Warnshuis, of Grand Rapids, who is also Secretary of the State Society. Dr. Warnshuis is also speaker of the House of Delegates of the American Medical Association and, having seen him preside over the National body, we expected that his editorials and reported addresses would be concise and carry extremely definite suggestions—and we found them even so.

The Departments of the *Journal* cover the range of activities of the Society. That of *Editorial Comments* is in addition to the formal editorial pages, and carries running comments on the medical news of the month, such as one thoughtful doctor would make to another during a casual conversation. There is a department devoted to Society work and its planned activities. The meetings of the County Medical Societies

are reported in an interesting style, but an editorial urges that more reports be sent.

The June number of the *Journal* of the Michigan State Medical Society contains a 28-page stenographic report of a conference of the secretaries of the county medical societies which was held in Grand Rapids on April 22nd, and lasted from ten until five o'clock. We have read the report from end to end, and have made marginal notes to indicate the points of the speakers, and we have thereby gotten the spirit and the point of view of the leaders who are promoting the practice of civic medicine in the State of Michigan.

The Conference was attended by fifteen county secretaries, three councilors, and four high officers of the State Society, including President Clancy, who presided. The total attendance was twenty-two.

The subjects discussed included the major activities of the State and County Societies, and showed that the officers of the State Society have practical plans which can be put into operation throughout the State. The program was as follows:

- 1 Activities of County Societies—Dr. J. B. Jackson, Chairman of the Council
- 2 The Spirit of Modern Organized Effort—Dr. F. C. Warnshuis, Secretary of the State Society and Editor of its *Journal*
- 3 What Are Desirable Features of the Scien-

tific Programs?—Dr G J Curry, of Flint, Secretary of the Genesee County Medical Society

4 Aids in Secretarial Work—Dr H L French, of Lansing, Secretary of the Ingham County Medical Society

5 Community Responsibility and the Work of the County Society—Dr D F Kudner, of Jackson, Secretary of the Jackson County Medical Society

6 Co-operation With County Medical Societies—Mr H G Smith, Executive Secretary of the State Medical Society

7 Round Table Discussions—Conducted by Dr Warnshuis

Each subject was presented briefly and concisely, and within five minutes, and then followed a general discussion. The topics centered around the specific major activities which are promoted by the State Medical Society. The talks might be divided into three groups of subjects

1 Inspirational, and the statement of fundamental ideals

2 The broad activities of the State Medical Society

3 The details of the execution of the plans by the State and County Medical Societies

Dr Warnshuis stated the four fundamental ideals of a County Medical Society to be

1 To enlist and interest all the eligible members of the profession in your county in the work of your County Society

2 To cause your Society to enhance the type of medical service in your community

3 To re-awaken the spirit of organized effort for the attainment of the mastery and honor of our profession

4 To beget professional fellowship

These are specific understandable ideals, and for the purpose of attaining them, Dr Warnshuis makes four specific suggestions which are the major activities of the State Society. These suggestions are as follows

1 Bring about better scientific programs for your regular meetings

2 Foster, inspire, and institute with the aid of selected members, an increasing number of public meetings for the education of the public in regard to scientific medicine

3 Adopt and develop a plan of periodic physical examinations

4 Join with and assume directing control of all public health work clinics and hospitals in so far as medicine is involved. (This last suggestion embraces what we have called the practice of Civic Medicine—The Editor)

A study of the minutes of the Secretaries' Conference gave us the impression that the four

major means for carrying out the activities of the State Society were

1 The Journal of the Michigan State Medical Society

2 The field work of the Executive Secretary

3 The Joint Committee on Public Health Education

4 District conferences

The Joint Committee on Public Health Education was formed in 1922 on the initiative of the Michigan State Medical Society. The organizations which were represented on the Committee are the State Medical Society, the University of Michigan, the Detroit College of Medicine and Surgery, the State Department of Health, the State Dental Society, the Michigan Tuberculosis Association, the State Nurses' Association, the State Conference of Social Work, and the Wayne County (Detroit) Committee on Education

The object of the Joint Committee is to supply popular lectures on medical topics to lay organizations. The Committee has about 200 speakers listed. During the past year, the Committee arranged for 271 lectures, at which the average attendance was 289 persons

At least nine district conferences have been held. The May Journal, page 268, and the June Journal, page 330, carry brief accounts of two conferences which are called Post Graduate Conferences. The programs consisted of all day scientific and clinical sessions, broken at noon by a luncheon by a Rotary or other civic club, and an evening popular session under the auspices of a civic organization, such as a Parent-Teacher's Association. The account in the June Journal concludes

"The ninth Post-Graduate Conference has brought more proof to the fact that Post Graduate Conferences that are conducted by the State Society in co-operation with councilor districts, and County Societies are what the members of these Societies desire"

When we analyze the suggestions made by the county secretaries, we find a wealth of details

Regarding programs, we note the following plans which have been used

1 Teams of members to arrange programs

2 Exchange of speakers with other Societies, or one Society to put on a program for a neighboring Society

3 Clinical programs like those of a staff meeting of a hospital

4 Social activities—lunches and picnics

As aids to secretarial work, we note

1 Getting committees to do the details of the secretary's work

2 Clerical assistance to attend to mailing and filing

3 Use of the telephone to get members to the meetings

4 Send accounts of the meetings to local newspapers

We note the following suggestions for meeting the community responsibility of County Societies

1 Close co-operation with the local boards of health

2 Medical publicity to the people

3 Periodic health examinations

4 Medical legislation (We find little said on this subject)

5 Charitable activities, especially those in co-operation with lay organizations. There was a lengthy discussion regarding orthopedic clinics conducted by Rotary Clubs, and the consensus of opinion seemed to be that local doctors should direct the medical phases of the clinics, and the laymen the business part, both working in harmony

Mr H G Smith, Executive Secretary, said that his work was to co-ordinate the activities of the County Societies by three general methods

1 Visiting County Societies and making medical surveys of the counties

2 Arranging district conferences

3 Legislative work during the session of the Legislature

Dr Warnshuis demonstrated his ability as a presiding officer by his management of the round table discussions, and his definite summary of the points brought out. After the subject of new members had been discussed for some time, Dr Warnshuis said that he would expect each county secretary to send him a list of non-members whom the Society would be willing to accept, and that he would write each one a personal appeal to accept an invitation to join.

We feel that our study of the minutes of the Secretaries' Conference and of accounts of the activities of the State Society that are printed in the Journal, has aroused our deep interest in the work of the Michigan State Society, and a desire to make the personal acquaintance of the leaders who are doing original work in the practice of civic medicine in Michigan. F O

## PROGRAM TEAMS

The Journal of the Michigan State Medical Society for July, 1925, page 401, contains a description of a new plan for programs of county medical societies. It is called the "Team Program Plan," which means that a team of from two to five men shall prepare a program on a given subject, and shall develop all phases of it, and be prepared to go to a neighboring county society and present it.

The plan was the result of the request of some of the smaller county societies that they be given assistance in making up their programs. The first call for assistance came from Alpena County on the northeast corner of the lower peninsula, whose population is 17,000 and is diminishing. The county society that responded was that of Bay County at the head of Saginaw Bay which has a growing city of 47,000 population. Bay County sent a team of five men who put on a

demonstration, to the great satisfaction of the doctors of Alpena County.

This plan is worthy of consideration by the Committee on Public Health and Education of the Medical Society of the State of New York. It benefits both the giver and the receiver, and stimulates interest in both societies. It solves to a great extent the problem of how to develop local talent. It is easy to send a speaker who will pour information over an admiring audience of doctors, it is quite another feat to get those same doctors to tap the springs of wisdom in their own midst. If only an individual doctor assumes to teach the rest, he is likely to be opposed, but if a team of doctors is appointed to present a subject in the name of the Society, the personal element is absent, and the Society is praised.

F O

## MONTHLY BULLETIN OF THE MEDICAL SOCIETY OF LYCOMING COUNTY, PENNSYLVANIA

We confess to some degree of envy when we received the June number of the Medical Bulletin, the official publication of the Lycoming County Medical Society in Pennsylvania. We had met the Associate Editor at the A M A meeting in Atlantic City, and he had told us that

his County Society had been publishing a Monthly Bulletin for years. We found that the current number is Volume Fifteen.

We then looked up the statistics of Lycoming County and found that its area is 1,220 square miles, and its population 83,100, distributed in

the city of Williamsport, 36,198, in seven villages, 29,388, while 17,514 people live outside the cities and villages

The city doctors number 60, those in the villages, 32, while 7 practice in strictly rural communities. Ten live out of the county.

The Lycoming County Medical Society has 109 members. So much by way of statistics.

The Bulletin consists of fourteen pages of live reading matter, and an equal number of advertisements largely of local firms. There are 275 copies printed monthly at a cost of \$83, which is largely met by the advertisements.

One of the first articles is one with the title "Attendance." It gives the number of members who have attended the regular monthly meetings of the Society during the last six months, and the average is seventy-five. Think of that, ye members of county medical societies in New York State!

Now, we chronicle a more surprising thing. The Editor considers it noteworthy that eleven members had failed to attend any of the six meetings, and then he proceeds to give the names and addresses of those 11 non-attending members!

The Bulletin carries a five-page description of the May meeting of the Society, and gives the names of the 80 members and 50 guests who attended the meeting. The program consisted of clinical demonstrations of 35 cases in the Williamsport Hospital by Drs. Thomas A. Shallow, Demonstrator of Clinical Surgery of the Jefferson Medical College, and Dr. Ross V. Patterson, Dean of the College. When we read this account, we felt that the Medical Society of New York State has a fine example to emulate in its promotion of clinical programs for county societies.

We also note that the Medical Society is actively engaged in the practice of civic medicine, as the following resolution shows:

*"Whereas*, The Lycoming County Medical Society has been given official recognition in the charter of the Williamsport Hospital, and thereby has assumed a definite responsibility in its affairs, and

*"Whereas*, it has always been the purpose of this Society to encourage any move that will develop scientific medicine among its members and provide better care for the sick, and

*Whereas*, we believe the effort now being

made by the staff and physicians of the Williamsport Hospital, and the hospital management, having for its purpose meeting the requirements of the College of Surgeons and the State of Pennsylvania in the way of detailed study of cases and case records to be a move that will increase the value of the Hospital in this community, provide better care for the sick, and encourage a higher type of scientific medicine among physicians practicing in the hospital,

*"Therefore, Be it Resolved*, that this Society, now assembled in regular session, and fully recognizing and accepting our responsibility in this matter hereby give our unqualified endorsement to this effort, and pledge our entire support to it.

*"Further, Be it Resolved*, That we urge each and every member of this Society who may have work in the hospital to give his personal support to this plan by following to the letter the plan of the staff and hospital to establish higher working standards in the hospital, and

*"Therefore, Be It Resolved*, That we assure the Board of Managers of the Hospital that we, as a Society, have assumed our proper share of the responsibility in this move and will at all times support the Board of Managers in their efforts to have this plan stand on its merits and be entirely acceptable to the College of Surgeons and the Bureau of Licensure of the State of Pennsylvania, and in the enforcement of any and all proper rules and regulations adopted to effect the desired end.

*"Further, Be It Resolved*, That this resolution be entered upon the minutes of this meeting and that a copy be transmitted to the Board of Managers of the Williamsport Hospital.

"By unanimous action, the Board of Directors recommend to the Society the adoption of the resolutions."

There is also a notice that at its next meeting the Society will elect two members of the Board of Managers of the Hospital.

The Bulletin carries an article on vomiting, a page describing the A. M. A. meeting, several poems, a page of personals, some jokes, and a cross-word puzzle.

It does us good to learn about the Bulletin and its most gratifying feature is that it is published by a medical society of an up-state county containing only 109 doctors. This is indeed a challenge to the county medical societies of New York State.

# NEWS NOTES

## THE MEDICAL FIELD SERVICE SCHOOL AT CARLISLE

We have just returned from a two-weeks' course for Medical Reserve Officers of the Army in the Medical Field Service School at Carlisle Barracks, Pennsylvania. We were of 254 medical officers, ranking from full colonels to lieutenants. Of these 21 were from New York State, as follows:

Colonels S. J. Kopetzky (the officer of highest rank in the School) and Harlow Brooks, of New York; Lieutenant Colonels W. G. Noe, New York, and H. A. Steckel, Binghamton; Majors F. W. Allen, Ithaca, S. Block, C. F. Claasson and E. M. Sutliff, of Brooklyn; Carl Boetiger, Forest Hills; E. C. Joyce, P. Lehman, L. H. Cornwall, P. I. Lipsott, H. C. Saunders, and U. Pascole, of Manhattan; B. S. Harwood, New Brighton; F. Overton, Patchogue; and M. Schley, Buffalo; Captain W. J. McGrath, Sylvan Beach; and Lieutenants E. Donheiser and T. Rosenthal, Manhattan.

There were also 530 medical, dental and veterinary students belonging to the Reserve Officers' Training Camps maintained in the professional schools east of the Mississippi River. These were taking a six weeks' course under the same field conditions as the medical officers.

All the physicians and medical students lived in tents in an alfalfa field, and followed a field service routine in all respects. We marched to classes and to meals, and all were on an equality with no distinctions as to rank. We sat on the grass while we listened to demonstrations in the field, and we stood up and recited our lessons in the class rooms. We studied the modern organization of the Army and the methods of work of its Medical Department. Most of us had seen

active service in the World War, and we were gratified to find that the deficiencies and intricacies of the methods used in the war have been simplified and standardized. We were amazed at the knowledge of details shown by our instructors, and by the clarity of the "clinical" methods of instruction as they demonstrated litters, and ambulances, and hospital tents, and sanitary appliances. A sham battle was staged on the golf field in order that medical officers might visualize an actual battle, with the air service and chemical warfare service assisting the foot troops. Another day aid stations were established on an imaginary battle front five miles away from Camp, and a number of soldiers were "planted" over the field tagged as if for wounds. Medical students of the R. O. T. C. found the men, gave first aid treatment, and transported them to aid stations, collecting stations and ambulances, and finally entered them in the hospital, exactly as they would do in a battle. The physicians of the Reserve Corps went with the R. O. T. C. boys, while the instructors of the School explained all the steps of the process. The "Clinical" method was followed in every respect.

We helped to get out a school publication called *Caduceus*, which contained a roster, jokes, cartoons and personal references, which will help the officers to recall a very pleasant fortnight spent in camp.

The Medical Field Service School is an essential part of the preparedness program of the Army of the United States. It also supplies information which is of great value to any doctor in his civic duties, such as organizing and managing hospitals. (See page 864)

F. O.

## BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society, held at Montefiore Hospital on June 17, was called to order at 9 P. M., the Second Vice-President, Dr. Goldberger, in the chair.

The following candidates were elected to membership: Abraham Louis Framer, Matthew S. Goldman, Benjamin Posinka, Lincoln M. Saulpaugh.

Dr. Podvin presented the following Report of the Building Committee:

The Committee has held several meetings within the past six weeks and considerable enthusiasm has developed in the plan of securing a permanent Home for the Bronx County Medical Society. Several plans have been advanced. One plan is

that we try to establish a Professional Building composed of the Medical Profession, the Legal Profession, the Dentists, and the Pharmacists. Another is that we erect a building for the use only of the members of our Society. The members of the Committee felt more favorable to the latter plan, and would only consider co-operating with other organizations when convinced that it would be impossible for the Society to build alone.

It was also decided, before we enter upon this very important venture, that we call a meeting of some of the prominent men in the Borough, outside of the medical profession, who have been interested in public affairs, in order to secure

their advice as to the best way to go about this project.

Before any definite action can be taken, it is necessary that we know whether or not the individual members of this Society are in favor of this project, and the only way we can find out is to ask them to contribute. Every member of the Comitia Minora and of the Building Committee has expressed a willingness to contribute to this fund. It was the intention of the Committee to place the matter before the members at this meeting, asking all members who will have been practicing medicine for at least five years in October, 1925, to pledge themselves to the donation of Fifty Dollars, payable in two installments, one half during 1925 and the other half in 1926, or the whole amount at one time, and all physicians practicing for less than five years to pledge themselves to the donation of Twenty-five Dollars, also payable in two installments. The Committee has decided to postpone action until the fall when it will be necessary to have the assurance of at least eighty or ninety per cent of the membership that it will co-operate in order that the project be carried on.

Dr Friedman, for the Committee on Public Health, reported that the Committee is working on various Periodic Health Examination Forms, and also requests additional names of doctors to volunteer for physical examinations.

The scientific session consisted of a clinical program arranged by Dr E M Boss and other members of the staff of the Montefiore Hospital, as follows:

1 Cases Illustrating Pain as the Initial Symptom of Various Nervous Disorders Walter M Kraus

2 Vascular Diseases of the Extremities, Illustrating Methods of Treatment Harold Neuhoof, Ira Cohen

3 Cases Illustrating Thoracic Operations in Pulmonary Tuberculosis Julius Gottesman, Jerome M Ziegler

4 Cases Illustrating Different Types of Hypertension Ernest M Boas

5 The Clinical Interpretation of Thoracic Radiograms (Lantern Slides) Maurice Fishberg

The meeting adjourned at 11 10 P M

I J LANDSMAN, Secretary

## SUFFOLK COUNTY MEDICAL SOCIETY

The regular semi-annual meeting of the Suffolk County Medical Society was held in the County Tuberculosis Sanatorium, Holtsville, on May 21, 1925, with President George H Schenck presiding, and 38 members present. The meeting was also attended by three visiting physicians, two lay officials, and five public health nurses.

Four new members were elected, and five members were accepted by transfer from other societies.

The following resolution was unanimously adopted:

*Resolved*, that the Legislative Committee of this Society be increased to five members, and that such Committee be instructed to interview the County Political Committees with a view of securing the nomination of candidates for election to the Legislature who will be guided in matters pertaining to public health and treatment of the sick by the Suffolk County Medical Society, and be it further

*Resolved*, that the members of this Society here present agree to use their influence in behalf of the candidates recommended by the Committee, and to vote in a non-partisan manner in case only one of the political parties will accede to the requests of the Legislative Committee of this Society.

The following is the membership of the Legislative Committee, as finally appointed:

Dr W H Ross, Brentwood, Chairman

Dr Guy H Turrell, Smithtown Branch

Dr J H Marshall, Southold

Dr George H Schenck, Southampton

Dr J S Ames, Babylon

A public health committee was appointed, consisting of Drs G H Turrell, David Edwards, and B P MacLean.

Dr John E Jennings, President of the Medical Society of the County of Kings, gave a ten-minute talk on Graduate Education, and outlined a plan by which the Graduate Education system of Brooklyn could be extended to Suffolk County as had already been done by the group constituting the South Side Clinical Society which centers about the South Side Hospital in Bay Shore (see this Journal, April 3, 1925, page 587, April 17, page 653, and the May issue, page 735).

Dr E P Kolb, Superintendent of the Tuberculosis Sanatorium, outlined a course of five clinical lessons on tuberculosis to be given to small groups of physicians who would agree to come to the sanatorium once a week. The plan was unanimously endorsed by the Society, and a class of eight was formed at once.

The Society discussed the matter of the appropriation of money by the State Society for the promotion of Graduate Education, and the following resolution was adopted:

*Resolved*, that this Society request the Council of the Medical Society of the State of New York to appropriate the sum of \$1,000 to each District

Branch to be used for the promotion of Graduate Education in the district

Milk problems in Suffolk County were scheduled for discussion during a ten-minute period, but the reports from several health officers showed such a widespread interest in the tuberculosis testing of cattle and the scoring of dairies that the discussion lasted an hour without a dull moment

A half-hour clinic on the twenty or more malnourished children in the Sanatorium was given by Dr E P Kolb, Superintendent, and Dr Frank H Richardson, Chairman of the Com-

mittee on Education of the Brooklyn Pediatric Society

The meeting consisted largely of animated informal discussions of topics connected with the practice of civic medicine. Several motions were carried thanking the several speakers, and at the end the Society adopted the following resolution of Dr W H Ross

*Resolved*, that the Society thanks the forward looking members who are waking up to the importance of the practice of public health

FRANK OVERTON, *Secretary*

### MEDICAL SOCIETY OF THE COUNTY OF ULSTER

The Medical Society of the County of Ulster held the April meeting at McCabe's restaurant

Communications were received from the Board of Managers of the Kingston City Hospital and the Kingston Academy of Medicine approving the Erie County resolutions on "Nurse Training"

On motion of Dr Norwood, the following resolutions were unanimously passed

"Resolved, That the Delegate of this Society to the State Society be and hereby is instructed to use every effort to secure action by the next House of Delegates looking toward the introduction by the State Legislative Committee of a bill embodying the Erie County resolutions on similar ideas regarding the training of nurses

"Resolved, That the Delegate be also instructed to work for the establishing in the State Society of a Standing Committee on Nurse Training,

whose duty it shall be to advise with the State Legislative Committee on all proposed legislation touching this question"

Dr Mary Gage-Day brought up the question of the Gorgas Memorial, and on motion of Dr Chandler, it was unanimously voted that the Medical Society of the County of Ulster give one hundred dollars (\$100.00) toward the memorial

Dr John J O'Leary gave a paper on "The Child and the Hospital" He emphasized the point that comparatively few children are cared for in hospitals. He also brought out the idea that so much of the meddling and interference by neighbors with the treatment would be done away with and the doctor would have the assurance that his directions would be intelligently carried out

MARY GAGE DAY,  
*Secretary Acting*

### MEDICAL SOCIETY OF THE COUNTY OF WASHINGTON

The Semi-Annual Meeting was held at Greenwich, May 26, 1925 Vice-President in the Chair

The Secretary presented the matter of the old Secretary's Book On motion, Dr Banker was authorized to select a suitable place to store the book and such other historic books as the society may possess

Dr Senftner from the State Department of Health, gave an exhaustive report on the use of antitoxin and toxin-antitoxin in the treatment and immunization of diphtheria

Following an adjournment for dinner, the afternoon meeting was called to order at 2 p m The President in the Chair

The Vice-President gave an address "On the

Diagnosis of Non-traumatic Acute Surgical Conditions of the Abdomen"

Miss Killrain asked for the opinion of the society on the proposition of extending the tuberculosis work to other branches of welfare work The President appointed Dr Davies Chairman of a committee to investigate the subject and report at the fall meeting

Drs Prescott, Rogers and Vickers gave a very thorough study of sixty cases of acute appendicitis as observed and treated in the Mary McClellan Hospital

Dr Morgan gave a very interesting paper upon the management of the tubercular patient as carried out in the Metropolitan Sanitarium at Mt McGregor, emphasizing the importance of rest

# THE DAILY PRESS

We started this Department of Daily Press in order to relay medical news items to our readers. We soon became interested in a study of the kind of items which the newspapers carried, and of the effect which the items have on popular thought and opinion. We recorded some of our observations and made suggestions as to how certain items could have been presented in a more effective form, so that the articles would carry more scientific information, and give the essential basis on which the information is founded.

Scientific information is likely to be cold and uninteresting, but yet a bit of it explains the reasons for certain actions taken by experts. If, for example, there is trouble over quarantine regulations, a statement as to how the disease spreads will illuminate and make plain the whole discussion. On the other hand, a scientific item on how the various diseases spread will be unprofitable, for no one will remember the details.

We have also studied the sources from which editors get their medical items.

A year or two ago the principal source was state-wide lay organizations which used the press for their propaganda, but for some months these organizations have made less use of the press. This is unfortunate, for one of the greatest values of lay organizations in public health is to educate the people regarding modern developments in medicine.

Local lay organizations are prolific sources of health items. Parent-teachers associations, tuberculosis committees, clinic organizations—all these do excellent work which is interesting to the people.

Official departments and boards of health are always sources of news. Court proceedings in health matters, and complaints of indignant citizens make spicy reading. Vital statistics and warnings of epidemics have less appeal. The official health authorities are making good use of newspaper space.

Professional health writers are also a source of items, especially of health columns. Many departments of health give out bulletins regularly which are widely used. They often lack force because they are propaganda rather than news. A vaccination article is usually mere propaganda, but it becomes vital news when a serious accident is ascribed to vaccination, or a smallpox outbreak develops.

The least used source of health items is the one from which we would naturally expect the greatest number of items to come. We refer to the doctors themselves. Last month

we found only eight clippings of articles that were supplied by doctors themselves, and this month we found only two or three. We believe that the ignorance of the public regarding medical matters is due very largely to the failure of the doctors to enlighten them through the most evident channels—the public press.

We ascribe the failure of doctors to give out health news to two causes:

1. A wrong interpretation of the principles of medical ethics.

2. A dislike to write composition.

Doctors complain loudly about the ignorance and indifference of the public toward medical topics. They make a correct diagnosis, but they do little in the way of treating the public to more information.

The day has passed when medical ethics prevent any doctor from giving out medical publicity items. The real reason why doctors do not give out medical items is that they just don't like the bother of writing them.

Two conditions are of extreme importance in effective medical publicity—1, timeliness, and 2, personality.

The great defect with most medical publicity is that it has no immediate practical application to the people. Departments of health send out columns of general information, but very little of it sticks, because no one is vitally interested in it. But let a diphtheria epidemic break out, and every person in the community is at once interested in antitoxin, Schick testing, and toxin-antitoxin immunization.

We believe that in every community there is always some medical topic in which the people are vitally interested. Therefore, it is wise for medical men to use these topics as subjects for publicity articles, and to write about them while they have a live interest.

The readiness of the people of a community to read medical articles may be compared to the fertility of a soil. When the soil of a community is freshly plowed and fertilized and watered, then is the time to plant the seed of medical truth and inspiration. Seed planted under such conditions will produce a crop a thousand times greater than that sowed broadcast without regard to the soil or season.

But the seed is of equal importance with the soil. Almost any medical topic is perfectly good, vigorous seed, but it lacks one little element to make it grow. That element is the personal name of some doctor who is known in

the community where the article will circulate. It is all very well to say "Truth is mighty and will prevail," and "We doctors can't use any newspaper tricks to get truth across to the public." The stubborn fact of the psychology of publicity is this **ALL NEWSPAPER PUBLICITY IS BUILT AROUND PERSONS**

Newspaper stories are mostly biographical. Someone gives a big party, and the reporter goes to great trouble to get a long list of names of those who were there. Why? Because the party itself is of small importance and interests few readers, but every reader looks through the list of those present, and will hail his friend the next day. "I see by the paper that you were at the swell party last night."

This same principal applies to medical publicity. For example, a county medical society has a meeting. This in itself arouses little or no interest. But the article gives the names of the doctors who were present, and everybody in the town wants to know what great thing has led his doctor to drop work to go to a meeting. The psychology is that the meeting must have been important if the doctors took the trouble to attend it, and when the people ask what it was all about, the reporter can tell them. The article as he prepares it will start out with about five lines telling what doctors were there, and then will follow fifty lines of a description of the meeting and the medical topics that were discussed. The presence of the doctor is the principal news item, and in relation to it the description of the work of the society is only secondary in the opinion of the editor and people.

We doctors may say that this is a foolish sort of psychology, nevertheless it is a scientific fact which doctors may do well to heed.

If medical publicity is to be accomplished, doctors must lend their names to the articles, and it is perfectly ethical for them to do so.

Now for a couple of concrete illustrations of what we mean.

The United States Army is the victim of unpreparedness which can be remedied by proper publicity. People do not know how many thousands of earnest peaceful men are attending army camps and army schools during this very Summer. If they did know, they would say "There must be a lot in prepared-

ness if Dr. Blank gives a month of his time in an army camp." The news that the doctor was in the camp is the strongest possible argument for preparedness, and a pacifist newspaper that would not mention preparedness will give half a column of space to the news of what the doctor did in the camp.

We were at the Army Field Service School at Carlisle, Pennsylvania, as we have reported on page 884 of this Journal, and we wanted to get a description of the camp printed in the Brooklyn Daily Eagle. We sent a description of the school to that newspaper and enclosed with it a list of the names of Long Island men who were there and a number of photographs of the school. The article promptly appeared with every name printed and a photograph of three doctors well known in Brooklyn and with only a few lines relating to the school. But the object of the article was well accomplished because the headlines featured the school. We presume some will be so unkind as to suggest that we sought publicity for ourselves, but no one has done so yet, and on the contrary many persons have commented on the school to which we went.

A second illustration. We attended a health officer class conducted by Dr. F. W. Sears in Watertown and lectured on the topics of medical publicity. In the afternoon we practiced what we preached and called on the reporters of the local newspapers and gave them a description of the course of instruction and of the interest shown by the doctors of Jefferson County. We have received clippings from four newspapers, all of which used the story because of the personal appeal of the doctors who attended the course.

The Committee on Public Health and Education may well consider the proposition that each county society shall have a committee on publicity whose duty it shall be primarily to send to every newspaper in the county an account of the meetings of the medical society, and, secondarily, to prepare and send out articles on live topics in which the doctors of the county are interested.

We believe that publicity efforts along this line will produce far better results than publicity along other lines. Effective health education cannot be dropped on a people from a central state authority. It must come from the doctors within the community. F. O.

## PROSTATECTOMY \*

Emphasizing the Present Day Factors of Safety

By PARKER SYMS, M D,

NEW YORK CITY

THERE is no problem in surgery that demands a more careful exercise of judgment and sagacity than the care of men suffering from prostatic obstruction. These patients are old both in years and in physiology. They have more or less advanced arterio-sclerosis and nearly all of them have more or less impaired kidneys.

Prostatic obstruction, if long continued, will result in death.

When these patients consult us, they are nearly all in a condition of impaired health, the degree depending upon the length of time they have been subjected to prostatic obstruction.

Thus we are operating, for the saving of life, upon individuals who are already below par, so it behooves us to be familiar with and to employ every possible factor of safety known to modern science, not some of them but all of them.

In this paper, I mean to deal mainly with certain dangers to the patient, and with the means at our command, of recognizing these dangers and of combating them.

When a patient suspected of prostatic obstruction comes to us for advice and relief we should proceed with the utmost discretion. We may be able to determine at once that he is not a fit subject for operation, and that palliative measures are all that can be applied to him. On the other hand, we may find that though he is in no condition for operation at the time being, judicious treatment may render him fit for operation.

A carefully taken history is of the utmost importance. We must learn when his first symptoms of prostatism showed themselves, and we must trace the progress of the disease from that time to the present.

The prognosis will often depend upon the duration of the disease and also upon the type of symptoms which have been manifest.

By rectal examination, we should determine whether or not he has an enlarged prostate, and

whether his prostate appears to be cancerous or not.

A gently introduced catheter should inform us if he has residual urine, and if so how much. Of course, his urine must be chemically examined.

The cystoscope should not be employed at this stage of the proceeding.

Examination should be made to determine the condition of his circulatory apparatus, that is to say, the function of his heart and the condition of his arteries. Blood pressure is an important item.

A Wassermann test and other examinations should be made to exclude cases of bladder crisis due to tubercles.

An X-ray should be taken to determine the question of calculus.

The most important thing to determine is the state of the kidneys.

In my general surgical work, I never operate upon a patient of advanced years without carefully studying the kidney efficiency. I regard anything less than 20 per cent "phthalein" recovery as contraindicating the use of a general anesthetic.

Constant specific gravity of 1012 or below is indicative of kidney pathology.

As to the blood chemistry, we regard

**Blood Sugar** 140 mg per 100 c.c. as the highest normal. All above indicates diabetes as a surgical complication.

**Creatinin** Above 2 mg per 100 c.c. as suspicious, 3 mg per 100 c.c. or above, contraindicating the use of a general anesthetic.

**Urea Nitrogen** 18 mg per 100 c.c. as the high normal, 20 mg per 100 c.c. or above, pathological, contraindicating the use of a general anesthetic.

With our prosthetics, however I feel one can be a little more liberal in his interpretations because we do not employ a general anesthetic. In other words, sacral anesthesia has given us an entirely new opportunity.

While we feel that we must give absolute heed to the specific gravity, to the concentration test, to the blood chemistry and to the "phthalein" output, we believe that a patient who can improve from a low level to one a little higher, even though his condition be not ideal, may be classed as a safe risk.

Except for the employment of sacral anesthesia and the method of operating, which we feel is of the greatest importance, there is nothing that influences the safe conduct of one of these cases more than the pre-operative treatment. In other words, the study and preparation of the patient for operation.

We are particularly indebted to Hugh Young for his early recognition of and for his unfailing insistence upon the importance of this point. There can be no doubt that his wonderful results have been due to two factors, viz, the safety of the perineal route, and the preparation of the patient by methods he has so ably described.

They are not due to the personal equation of the operator, for Young himself says that he (the same operator), had unsatisfactory results as long as he followed the supra-pubic route.

Young emphasized the importance of gradual, not sudden decompression of the kidney pelvis. He accomplishes this by means of systematic and gradual catheterization, or by the employment of an indwelling catheter.

Personally, I feel that such catheter passed through the perineum is preferable to one passed through the urethra.

Without going into details of the mechanics and physiology of back pressure at this time, it is sufficient to state that residual urine, especially in increasing quantity, and obstruction at the bladder neck, resulting in frequent urination and retardation and straining, causes an abnormal amount of back pressure against which the kidneys have to work. Young has correctly interpreted this condition and has given us the proper means of coping with it.

It is this condition which has misled men to adopt the two stage operation as a routine. I have always maintained that a two stage operation should not be employed as a routine procedure. It should be reserved for those few cases where it is a necessity. Performed indiscriminately, it is a menace.

When preliminary drainage for decompression is a necessity and cannot be brought about by systematic catheterization, or accomplished by means of an indwelling catheter, the bladder should be drained by means of a perineal section and not by the supra-pubic route.

Experience has taught us that in cases which need decompression, sudden relief of pressure is often dangerous. With an indwelling catheter,

one can regulate the pressure. With drainage through the perineum, the same holds true, the bladder sphincter being intact. When the bladder is opened supra-pubically, there is no chance of restoring pressure if it is found desirable to do so.

As far as the sudden and unwise relief of back pressure is concerned, supra-pubic drainage subjects the patient to all the dangers of a one stage prostatectomy without preparatory treatment. How often has a patient succumbed to uremia owing to the sudden decompression? In these cases it should be gradual.

If one uses a retention catheter through a perineal urethrotomy, he can control it absolutely. Perineal drainage can be established by means of local anesthesia with practically no risk to the patient. The urethra can be opened on a lithotomy staff and a self-retaining catheter inserted, in one or two minutes. The back pressure can be reduced gradually and its effects carefully watched and controlled.

When, and if we feel the patient has reached his optimum and his condition is good enough for operation, it can be accomplished by simply enlarging the perineal wound and following out the proper procedures.

Young has also stressed the importance of administering large quantities of water.

Of course, the bowels should be thoroughly emptied and the patient's condition tested from time to time to see whether or not he has reached a state justifying operation.

#### *A further word concerning the cystoscope*

I do not wish to be thought lacking in appreciation of the cystoscope. I regard it as one of the most essential instruments of precision at our command. I have owned and employed the cystoscope from the earliest days of its perfection, but I do recognize and must call attention to the danger of its indiscriminate employment in cases of prostatic obstruction.

To pass a rigid, almost straight instrument through a tortuous, obstructed canal, into an infected bladder, is often a serious and dangerous procedure.

When there is occasion to use the cystoscope in cases of prostatic obstruction, I like to employ it at the time of operation, then, opening and draining the bladder will give one the greatest safety as far as infection is concerned. This is no theoretical objection on my part, but is based upon actual experiences of men of undoubted skill in the use of this valuable instrument.

So much for the examination and the preliminary care of the patient, let us now consider certain dangers which have attended prostatectomy in the past, and see what we have been able to do in the way of avoiding or combating them. In other words, let us further consider the factors of safety to the patient.

The most common causes of death have been uremia, pneumonia, embolism, hemorrhage and infection resulting in sepsis and in phlegmonous inflammation of the wound

The subject of *uremia* has really been covered in the preceding paragraphs relative to kidney deficiency, and the means employed to prevent and to correct it

Having eliminated those patients who cannot be rendered fit for operation, and having given careful attention and treatment to the others so that we shall be operating upon a class of patients who may be considered good, or at the worst, fair risks, will have gone a long way toward reducing the percentage of deaths from uremia, but there is no doubt that the administration of ether or any other general anesthetic to a patient with lowered kidney function is a menace. Thus the employment of sacral anesthesia is one of the greatest factors of safety as far as uremia is concerned

*Pneumonia* has stood prominently as a cause of death. It was largely due to the administration of a general anesthetic and to prolonged confinement in bed. Now we can expect it to be of infrequent occurrence, having done away with these two danger factors. We employ sacral anesthesia instead of a general anesthetic, and if we perform a median perineal prostatectomy we can expect to have the patient out of bed within 24 to 36 hours after operation

*Embolism* is a frequent complication of supra-pubic prostatectomy, and I am surprised to learn that Young has found it a frequent cause of death among his cases. As it has been of the rarest occurrence in my experience, I feel there must be some reason for this rarity in the method of operating. Of course, embolism depends upon injury to and infection of veins, resulting in thrombosis, the embolus coming from the clot. In supra-pubic prostatectomy, injury to the large venous plexus which lies *above* the prostate is unavoidable, and as the drainage must be uphill and incomplete, in an infected area, it is not surprising that embolus should occur rather frequently. Perhaps the methods of median perineal prostatectomy, where the wound is left open and inflammation practically never occurs, may account for the fact that embolus has been an almost unknown complication in my experience

*Hemorrhage* is and always has been a severe bugbear in connection with supra-pubic prostatectomy. The literature is full of methods and appliances which have been devised for its control. The large venous plexus lying *above* the upper part of the prostate is one reason for this complication of supra-pubic as distinguished from perineal prostatectomy. In perineal prostatectomy with a properly performed enucleation, hemorrhage is a complication not to be dreaded for it is practically not encountered. All that is

necessary is to avoid the artery of the bulb and to avoid lacerating and tearing the sheath which covers the prostate

*Infection, sepsis* and *phlegmonous inflammation* are, of course, more liable to occur in such an unsurgical wound as a supra-pubic prostatectomy results in, than in such a proper surgical wound as results from a perineal prostatectomy. Personally, I have had but one such case in my entire list

If what has been stated above is true, it will be seen that perineal prostatectomy performed under sacral anesthesia is the safest procedure we have at our command. Perineal prostatectomy is conceded to show a lower death rate than supra-pubic prostatectomy

(For details as to the administration of sacral anesthesia, see foot notes)

As to the comparative safety of sacral anesthesia, as compared with general anesthesia, there cannot be the slightest doubt. Sacral anesthesia is so thoroughly accredited and has been so fully described that I need not do more at this time than to emphasize its value and to urge its employment where it is applicable

The injection of a sufficient amount of a proper solution of novocain into the sacral canal will produce anesthesia of the perineal region, and will enable one to perform a perineal prostatectomy without pain to the patient. The amount injected should be between 30 and 40 c.c. of a 1¼ per cent solution of novocain. Personally, I believe we shall have full success with the caudal injection, which is much less complicated than the para-sacral. The latter can always be instituted if the anesthesia is not found to be perfect after a single injection has been made

The anesthesia should be perfect. Scholl and Meeker are correct when they claim as failures cases where a general anesthetic has to be supplemented

The anesthesia passes off slowly so that the first few hours are rendered comfortable. The patient is returned to bed in a good condition and able to eat a light meal

Our experience has led us to reduce the after treatment to the greatest simplicity. We used to do too much. Now we do very little

Formerly we irrigated a great deal, in our attempt to keep the bladder free of clots, but we have come to the conclusion that irrigation promotes oozing and we have less trouble if we do very little of it, so we scarcely irrigate the bladder. If the tube becomes clogged and there is difficulty in cleaning it, we remove it. I have done this an hour after the operation. At the time of operation we are careful to place the temporary suture so loosely that blood will not be dammed back into the bladder

We used to feel that it was essential to pass steel sounds repeatedly with the idea of prevent-

1—Posterior surface of sacrum showing needle in hiatus sacralis

2—Showing simple median incision in perineum. There is no dissection and but a single sweep of the knife

3—Knife entering the lithotomy staff and dividing the membranous urethra.

4—Showing Sims' rubber tractor within the bladder, pulling prostate toward the surface. (I am now using Young's tractor instead of my own.)

5—Showing Sims' tractor in situ. Incision in sheath of prostate is shown ready for enucleation

6—Showing Young's tractor in situ. Incision in sheath of prostate is shown, ready for enucleation

ing stricture We now feel that stricture never results from our operation, and all that is necessary is to pass a sound or silver catheter once through the urethra into the bladder, simply to be sure that the channel is open

It there be delay in the urine coming through the urethra, a sound may be passed into the bladder through the urethra on the sixth and seventh day

In a typical case, we remove the tube and most of the packing within 18 to 24 hours from the time of operation. If the patient is in fair condition he is then allowed out of bed. He is usually able to sit without much discomfort, and he is able to walk about. Usually his bladder condition will be satisfactory from the first. The remainder of the packing is removed on the second or third day, and but a light packing, if any, is replaced

After the gauze and tube are taken out, we irrigate through the penis, allowing the water to flow out of the wound. This should be done more or less frequently at first

The patient is usually able to hold his water and to go about under his own power within a few days. I have had most of my recent cases come to my office for treatment after the fifth or sixth day

The wound will usually be completely healed in the third week. Since we have stopped excessive packings and manipulations we have had no delay in the closure of these wounds

If the bladder needs treatment on account of established cystitis, I wash it with a 1-5000 solution of silver nitrate, passing my silver catheter through the urethra, not through the wound

*Epididymitis* we try to prevent by keeping the urethra clean and by keeping the testicles well elevated, at first with adhesive plaster and later with the suspensory bandage

*Final Results* A satisfactory result after prostatectomy will mean that we have a patient restored to comparatively good health. He

should be much improved in every way. As he has been relieved of residual urine and back pressure, of obstruction and difficult urination, his kidney functions should be much improved

The operation cannot be regarded as a success unless bladder function has been restored to a practically normal condition. The patient should be able to hold his urine, his bladder should have a good capacity, and he should be able to empty his bladder. He should not have residual urine. It has been claimed by some that the final function of the bladder will be better after a supra-pubic than after a perineal prostatectomy. I have no reason to believe this to be true. I have seen many more bad results following supra-pubic than perineal prostatectomy, though I have performed very few supra-pubic prostatectomies

I fully believe that the internal sphincter, which is a true sphincter, is the real bladder sphincter, that the external sphincter, so called, which, by the way, is not a sphincter, is but supplementary, but this is a question, the details of which I shall not go into at this time, for I hope to do this later

When I entered this field of surgery, in 1898, prostatectomy was of dubious worth, carrying with it such a high mortality that by some it was considered an unjustifiable procedure. Today, it has been elevated to one of the highest places in surgery

Improved methods of pre-operative care and preparation of the patient, sacral anesthesia and much improved operative technique, in both supra-pubic and perineal methods, have placed prostatectomy in the foremost ranks of surgical achievements, both as a means of prolonging and of saving life

### INHALATION VS REGIONAL ANESTHESIA FOR PROSTATECTOMY

By OSWALD SWINNEY LOWSLEY, A.B., M.D., F.A.C.S., and H. EARL ROGERS, A.B., M.D.

From the Department of Urology (James Buchanan Brady Foundation) of the New York Hospital  
NEW YORK CITY

THE question of prostatectomy has occupied the earnest attention of surgeons for many years. The introduction of ether and chloroform anesthesia opened the avenue of progress in this type of surgery as it did for all surgery. The next great advance was the gradual realization that the most important thing about a prostate operation was the preliminary drainage of the patient's bladder before the removal of the gland was accomplished. This procedure

still remains the most important part of any method of prostatic removal

Our experience teaches that suprapubic cystotomy after suitable preliminary decompression is by far the best method of pre-operative drainage. Its superiority lies in the fact that the drainage is complete, permits the oedema of the gland to be diminished, thereby lessening the extent of the hemorrhage at the time of operation.

Catheter drainage per urethram does not have the beneficial effect, and, in fact, there is just enough irritation caused by this foreign body

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 13 1925

lying in the prostatic urethra to lead one to believe that the patient absorbs a little toxin and does not reach the maximum of renal efficiency noted by the suction drainage through a suprapubic double draining tube as suggested by Kenyon and practiced in the New York Hospital

The last great step in the progress of surgery of the prostate is the introduction of regional anesthesia for its removal. This method, first originated by F Cathelin and Durant in 1902, who relieved sexual neuroses and incontinence of urine by epidural injections into the sacral canal, has been improved by many workers until now we are able to accomplish any type of prostatic operation by its use. The method in use has been described by the author and was popularized in this country by Labat

In order to be certain of results one must tabulate, unselected, consecutive cases and review the situation. This study is such a tabulation

The first 100 consecutive cases of prostatectomy under regional anesthesia are compared with the last 100 consecutive cases under inhalation anesthesia (gas-oxygen). Unfortunately the two series were not subjected to exactly the same conditions, as not all of the cases were cared for in the Department of Urology. We feel very strongly that the prostatic is much better off when cared for by doctors, nurses and orderlies who are experienced in their care and who are supplied with the proper food and appliances necessary for such attention

Those patients included in the series of prostatectomies performed under general anesthesia who were not treated in our department were cared for in private or special hospitals under such conditions that were as near like those prevailing in our department as could be arranged

#### FIRST SERIES

TABLE SHOWING 100 CONSECUTIVE PROSTATECTOMIES PERFORMED UNDER INHALATION ANESTHESIA\*

#### SECOND SERIES

TABLE SHOWING 100 CONSECUTIVE PROSTATECTOMIES PERFORMED UNDER REGIONAL

*Summary of Results*—By a review of the above tables it will be seen that in the first series the oldest patient was 85 years of age, the youngest 30—the average age 64.65 years—While the average in the second or regional anesthesia series was 65.25—the oldest being 82 years of age and the youngest 49

In the inhalation group there were

16—Two-stage suprapubic prostatectomies

8—One-stage suprapubic prostatectomies

38—Two-stage perineal prostatectomies

38—One-stage perineal prostatectomies

In the regional group there were

2—Two-stage suprapubic prostatectomies

0—One-stage suprapubic prostatectomies

98—Two-stage perineal prostatectomies

0—One-stage perineal prostatectomies

Sixty-eight per cent of the regional anesthetics were 100 per cent perfect, 2 received 98 per cent anesthesia, 12 received 95 per cent, 8 received 90 per cent, 6 received 85 per cent, and 4 received 75 per cent. This estimation is one made by the resident urologist and not by the anesthetist. The four very poorly anesthetized cases required less than one ounce of ether to make the operation possible. The rest listed as less than 100 per cent required even less. Those recorded as 98 per cent and 95 per cent complained but refused to smell ether, aromatic spirits of ammonia, essence of orange or other aromatic solutions

*Shock*—A study of the blood pressure in both series is most interesting. In the inhalation anesthesia the blood pressure is always considerably elevated. The extent of the rise varied from 30 mm -Hg to 90 mm -Hg during the anesthesia. Following operation there is always a drop below normal in the first series, almost all cases showed a fall below 100 mm -Hg. Ten required gum glucose or saline infusion in order to prevent shock, 23 definitely went into shock, one had a blood transfusion, one had a saline solution, 31 had unusual hemorrhage. In the regional series three cases went into profound shock after operation, two were given blood transfusion, the third case of shock died 18 hours after operation in spite of the most energetic methods of combating shock, including the administration of stimulants, gum glucose solution and other recognized procedures

*Complications Other Than Shock*—General anesthesia—calculi in posterior urethra, 1, slow convalescence, 1, uremia, 4, pneumonia, 2, myocarditis, 2, epididymitis, 4, infected wounds, 5, pulmonary emboli, 1, multiple abscess of kidneys, 1, diabetes, 1, faded away, 1, 76 of this series had no complications

Regional anesthesia complications were not so numerous, 87 cases had no complications whatever. Pulmonary embolus, 12th day post-operative, 1, hemorrhage relieved by gum glucose, 2, pyelitis, 2, Epididymitis, 2, calculus in bladder, 1, recto-urethral fistula, 1, cellulitis of scrotum, 13th day post-operative, 1, uremia, 1, phlebitis, 1

*Length of Stay in Hospital After Prostatectomy*—General anesthesia group, the longest post-operative stay in the hospital was 90 days, the shortest 10—average 33 days. The regional group shows an average post-operative stay of 22.7 days, the longest being 56 days, the shortest 10 days

*Mortality Record*—The death rate for the inhalation anesthetic group was 14 per cent, the causes of death were as follows

3 Died from hemorrhage and shock (2 one-day P O and one 16-day P O)

4 Died from pneumonia (one day, 3 days, 10 days and 19 days P O)

\* For Tables see pages 895 to 900

## REGIONAL ANESTHESIA SUMMARY

Oldest Patient	82 Years	Average	65 25 Years	Number of Patients Given Gum Glucose	2
Youngest Patient	49 Years			Number Had Marked Hemorrhage	2
Longest Stay in Hospital—P O	56 Days	Average	22 7 Days	Number Had Shock	4
Shortest Stay in Hospital—P O				Number of Deaths	3

4 Died of uremia (one day, 3 days, 40 days and 43 days P O)

2 Died of myocarditis and cardiac failure (14 days and 30 days P O)

1 Died of pulmonary embolus (93 days P O)

Of the 14 deaths the last three are more or less accidental, although the operation must be considered as the cause of death. Three died as a direct result of the operation from hemorrhage and shock. Four died of pneumonia and four of uremia. The inhalation anesthesia can be accused of having a direct bearing in 11 of the deaths.

In the regional anesthetic group there were only three deaths, one from hemorrhage and shock (18 hours), one following infection and cellulitis, 13 days P O, one from pulmonary embolus, 19th day P O.

TABLE SHOWING COMPARISON BETWEEN THE TWO METHODS

	Average Age	Unusual Hemorrhage	Shock	Complications	Average Post Oper Day	Mortality
Inhalation Series	64.65	31	23	24	33	14
Regional Series	65.25	6	3	13	22.7	3

## THE PRESENT STATUS OF INSULIN THERAPY \*

By ELLIOTT P JOSLIN, M.D.

BOSTON, MASSACHUSETTS

**I**NSUFFICIENT Use of Insulin by the General Practitioner. The chief defect in the present status of insulin therapy is the lack of its use by the general practitioner. If he fully recognized what he could accomplish for his patients with insulin, he would not do without it. Insulin has metamorphosed my practice. It has made the care of the diabetic an ever-stimulating pleasure rather than a constant Puritanical duty. What insulin has done for one doctor it will do for any doctor who employs it after having learned the dosage and method of administration, and the relation it bears to the diet of the patient.

**Distribution of Doctors' Emergency Insulin.** So strong is the evidence that physicians would wish to use this new drug, insulin, if they had it and were accustomed to it that the Board of Health of the State of Massachusetts will distribute this month to each doctor in the State outside of Boston a bottle of Doctors' Emergency Insulin, which can be carried in the doctor's bag. This distribution has been made possible through the generous gift of your fellow citizen, Mr. John D. Rockefeller, Junior. It came about in this way. Some three years ago Mr. Rockefeller gave to individuals in various communities liberal sums of money to be used for the purchase of insulin for needy patients and for the instruction of doctors and nurses in its use. Fifteen thousand dollars was the sum assigned to Boston and, because unsolicited, was all the more welcome. Our saving New England propensities have made this sum last, although during this interval patients at five different hospitals in the city have been assisted by it. Boston doctors have benefited from it. But

one day it came to my attention that one of my diabetics in Newfoundland died, partly because the boat, carrying his insulin, was late. Then I heard that another patient in Caribou, Maine, was in extremis with erysipelas, and no insulin was to be bought in the town. Finally a doctor called me up early one morning, stating that he had been called the previous evening to a patient conscious and breathing a little heavily, but now in coma. He had no insulin the night before, could not get insulin, in fact had never given insulin, and at the moment was caring for another woman in active labor. Some hours later insulin was secured. The country doctor did the best he could, caring for the two patients living far apart, but as might be expected, the coma case died.

When these incidents were related to Dr. Kelley and Dr. Bigelow, of the State Board of Health, they eagerly accepted a gift of insulin for distribution under their supervision to physicians outside of Boston. I do not believe diabetic deaths or deaths from diabetic coma will cease in Massachusetts, but if such deaths occur it will not be because the first and therefore best dose of insulin is not available. Your Mr. Rockefeller has put a bottle of emergency insulin into the bag of every doctor outside of Boston in Massachusetts.

**What Insulin Has Accomplished.** It is very easy to say that insulin allows the diabetic patient to become efficient again—to teach, preach, work, play, and even grow and contribute to the support of his family—but such statements, though true, are generalities, and what is wanted by doctors who have used insulin little or not at all, are concrete facts. These are therefore submitted in the form of reports upon certain groups of diabetic pa-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 13, 1925.

tients acknowledged by all to be serious and by a few specific instances First let us take diabetic coma

*Evidence from Treatment of Diabetic Coma* Between January 1, 1923, and April 1, 1925, there have been treated at the New England Deaconess Hospital 33 cases of diabetic coma with two deaths from this complication During the preceding quarter century I have had but fifteen recoveries among patients already in or, perhaps better stated, less far advanced in coma A similar experience has just been published by Nellie B Foster, and many hospital physicians have lists of such cases But these hospital recoveries are not to the point Dr Shedd, of North Conway, New Hampshire, saved his case of coma, Dr Kilbourn, of Groton, Massachusetts, detected and saved his, and, best of all, old Dr Towle, of Dorchester, Massachusetts, who graduated 48 years ago from a New York medical school, saved his coma case, too When called to the unconscious girl, he recollected a diabetic, a doctor's widow, who lived hard by, begged from her a bottle of insulin, injected the whole of it, and when, to his astonishment, he saw it was doing his coma case good, secured the widow's last cruse and gave the whole of that, too, and then sent his patient to the Peter Bent Brigham Hospital, where Reginald Fitz finished the job

In your home city or town I daresay your patients, too, are talking about the coma case you likewise have saved However, if you have not had that pleasure, I warn you lest some young medical upstart or wise medical virgin arrive on the scene and enter into fame merely because of a bottle of insulin in his or her doctor's bag

*Evidence from the Treatment of Children* The children show what insulin will accomplish Formerly they died, now they live—for how long one cannot say, but the facts are these Prior to 1914 the duration of life of my 25 children with onset of diabetes under 10 years of age was 12 years In contrast are my first 16 cases of similar age to take insulin These have already lived not only three times as long but still are alive

*Pathological Evidence* This prolongation of life of diabetic children is of more significance than at first appears The first year of diabetes is the diabetic's danger zone Once passed, even under non-insulin treatment, he often lives for years A pathological explanation of this has recently been found in a third group of my cases Shields Warren and Howard Root, working under the guidance of Professor F B Mallory, have found some evidence, based upon 26 autopsies of my cases, that regeneration of the islands cells of the

pancreas takes place *pari passu* with the duration of the diabetes Their first article, dealing chiefly with the pathological aspect of the question, will be published in the July number of the Journal of Pathology, and a later article will correlate pathological with clinical findings If future work confirms their conclusions, we can feel that if we prolong the lives of our patients a few years we shall afford time for a certain amount of regeneration of the pancreas The Toronto case reported by Boyd and Robinson is perhaps the first and surely the most heartening in this connection, and is of especial importance because of the many investigators who attested the presence of regeneration in the tissue submitted for their opinion

*Specific Instances of Improvement with Insulin* A few specific instances to show why doctors cannot afford to neglect to use insulin Miss M, a nurse, Case No 1542, my first patient to take insulin, has employed it 34 months Her weight had fallen from 157 pounds to 74½ pounds, and for nine months she had not gone down a flight of stairs She now weighs 129 pounds and is earning her living Freddie G, Case No 1616, who was brought to the hospital on a cushion on October 4, 1922, after three years of diabetes, is now eleven years of age, has doubled his weight, and recently in one month grew an inch in height He seldom misses a day at the public school A girl, whose condition was formerly so deplorable and so tragic that I can't describe it, is now happy and attractive and for fun has become a teacher

*The Standard Diabetic Diet* The standard diet of a diabetic patient of moderate severity weighing 50 kilograms (110 pounds) is as follows

Food Grams	Carbohydrate Grams	Protein Grams	Fat Grams
5% Vegetables, 4 portions 600 grams or 20 ounces)	20	10	0
3 very small Oranges (300 grams), or			
3 medium sized Grape Fruit (600 grams)	30	0	0
Oatmeal, 1 saucerful (dry weight 30 grams, cooked weight 240 grams)	20	5	2
Uneda Biscuits, 2	10	1	1
Cream 20% butter fat, ½ pint (240 grams)	8	8	48
Eggs, 2	0	12	12
Bacon, 4 crisp strips (30 grams)	0	5	15
Butter, 3 portions (30 grams)	0	0	25
Meat, 1 small portion (60 grams)	0	16	10
	88	57	113
	4	4	9
	352	228	1017

Total Calories, 1,597

If the patient is not sugar free on this diet, it is easy to reduce the carbohydrate by 15 grams by halving the fruit, by another 10 grams by halving the oatmeal, by another 10 grams by omitting the Uneeda biscuits. Thus the carbohydrate becomes 53 grams, and below this quantity today we seldom ask our patients to go. If the carbohydrate is to be increased, remember a banana contains 20 grams, a shredded wheat biscuit 23 grams, and if your patient is so reliable that you can allow food as indefinite in size as potato or bread, remember that size for size potatoes are like bananas and toast like shredded wheat.

Younger and heavier patients need more protein, the little children even 3 grams per kilogram body weight, the very old, the very severe, the case complicated with Bright's disease, proportionately less. Fat is given for weight and efficiency. When the urine is sugar free and the protein is 1 gram per kilogram body weight, it is allowable to give 3 grams of fat for each 1 gram of carbohydrate, but if the protein is reduced to two-thirds of 1 gram per kilogram body weight, the fat may quadruple or quintuple the carbohydrate.

*Insulin Indications and Dosage* If a diabetic patient is not efficient, happy, and sugar free on a diabetic diet, he needs insulin. And did you ever think how much 5 units will do? It will allow at least 5 grams additional of carbohydrate, possibly 10 grams, but for our purposes let us say 5 grams. That means one Uneeda biscuit, but, to match the carbohydrate which it contains in fat, you can allow 15 grams, or one half ounce, of butter. These two foods are equivalent to 140 calories, nearly 10 per cent of the standard diet prescribed. Such calculations as these show how much a few units will do.

Small doses of insulin only are required by the majority of those diabetic patients who need insulin, besides diet, to keep sugar free and maintain strength. Few children, even after years of diabetes, demand over 15 or 20 units in 24 hours. None of my cases receives regularly over 60 units a day. As a rule the insulin is given twice daily, often once, less often three times, and very, very rarely four times. By testing four specimens of urine—namely, that of the morning, that of the afternoon, that of the evening, and that of the night—and comparing the results with the distribution of the carbohydrate in the diet and the dosage of insulin, one can soon arrive at the proper quantity of each to be administered. In the presence of the high metabolism of an infection or of exophthalmic goitre, during convalescence from operations, and during periods of abstinence from food, whether voluntary or involuntary, it is always the part of

caution to increase the frequency of giving insulin. Simultaneously the size of the dose should be changed up or down in accord with the result of the examination of an individual specimen of urine obtained at the time of each injection. Under these conditions insulin is given to offset the food derived from the metabolism and not from meals.

*Hypoglycemia Seldom Dangerous* An overdose of insulin seldom results in death. I do not recall 5 such having been reported in the United States either publicly or privately. A few units are dangerous in the course of diarrhoea and severe inanition, and once we had a noisy reaction in a feeble old man who was taking 100 grams carbohydrate. This occurred seven hours after the last of three meals, preceding the first of which the patient was given 5 units. It is unnecessary to speak of the treatment of a reaction. Of some 2,000 diabetic admissions it has been felt necessary to give glucose intravenously upon but three or four occasions. Others have recovered with the juice of an orange, one or two lumps of sugar or teaspoonsful of syrup.

The latency of the symptoms of a reaction, both in children and in adults who have used insulin long, deserves a word. Shortly before a meal they may feel a little weak and uncomfortable, yet not evince the symptoms characteristic of an insulin reaction, such as hunger, trembling, sweating, or even diplopia. An examination of the blood reveals an encouraging hypoglycemia, encouraging because it suggests a regeneration of the pancreas, an increased ability to burn carbohydrate. In years gone by we were on the watch for diabetics to grow worse, now we must be alert to detect their growing better.

*Abscesses* Abscesses do not result from the use of insulin save when preceded by extreme carelessness. To this statement I must make one exception—namely, that of a colored woman who developed an abscess in the hospital. Neglect of diet, very large doses of insulin, its administration constantly in the same site, and (Geyelin) the use of dilute rather than concentrated preparations, have been the causes.

*Omission of Insulin without Curtailment of Diet the Greatest Danger* The diabetic who takes insulin is walking on stilts. If he suddenly gives up the stilts, he is in grave danger of a rude fall unless he reduces his diet one-third or to that amount of food which he can tolerate without insulin. It is infinitely safer to give insulin than to withhold it.

*Coma and Rules for its Treatment* Overeating leads to diabetes, overeating makes the diabetes worse, overeating invariably precedes coma, though sometimes, as in

fever and in goitre, the overeating is endogenous in character—namely, of the body and not of extraneous food. Coma still is such a menace and can occur so easily in a careless diabetic taking insulin that our routine measures for the treatment of coma at the New England Deaconess Hospital may be of interest. These will appear this month in the second Boston number of the *Medical Clinics of North America* as a part of an article upon *Diabetic Coma and Its Treatment* written in association with Dr. Howard F. Root and Dr. Priscilla White.

*Rules for Treatment of Diabetic Coma in Force at the New England Deaconess Hospital April, 1925*  
*Duties of Nurse*  
*A. Preparations for Reception of Patient*  
 (1) A warm bed with blankets in place of sheets and at least four hot water bags.  
 (2) The necessary equipment in readiness at the bedside for catheterization, for a soapsuds enema, for gastric lavage, for subpectoral infusion of normal saline, for administration of caffeine and insulin.

*B. Care of Patient*  
 (1) Secure specimen of urine, by catheter if necessary. A specimen of urine is to be tested for sugar and di-acetic acid every hour until recovery. If a self-retaining catheter is to be left in the bladder, urotropin 10 grains should be given every four hours for three doses.  
 (2) Hourly records of the pulse and two-hourly records of the respiration rate and temperature are to be kept.  
 (3) Enema.

*Duties of Physician*  
*A. Examination of patient*

*B. Constant attendance until the crisis is passed*

*C. If diagnosis of coma is confirmed, write necessary orders for treatment with especial reference to (1) gastric lavage, (2) the method and rate of administration of liquids by mouth, rectum, or subcutaneously, (3) the diet, (4) caffeine, and (5) insulin.*

The purpose of gastric lavage is to prevent or relieve gastric dilatation.

Liquids by mouth must be given hot and at a rate not to exceed 100 cubic centimeters an hour. Liquids by rectum—salt solution, black coffee, or tap water—may be given every two hours for two doses and thereafter every four hours. If the patient is dry, unhesitatingly give salt solution subpectorally, except in the

presence of pulmonary rales, when it may be given under the skin of the thighs. If the intravenous route is preferred, give very slowly 250 to 500 c.c. of normal salt solution, and no more until at least an hour has elapsed. One c.c. of adrenalin from a sterile ampoule may be added to the salt solution when the systolic blood pressure is below 90.

The diet in the first 24 hours should not contain more than carbohydrate 50 grams, protein 25 grams, and fat 25 grams, unless warranted by unusual improvement of the patient. This is represented by oatmeal 30 grams dry weight, equivalent to 500 grams as thin gruel, orange juice 250 grams (the juice of two small oranges), the whites of 5 eggs, and medium cream 120 c.c. Broths, coffee, tea, cocoa shells, may be utilized as vehicles for the above.

Caffein sodium benzoate is injected subcutaneously, 5 grains every hour for four doses and thereafter as indicated.

The gravity of the coma is evidenced by the degree of stupor, the exhaustion of the patient as shown by a rectal temperature of 95° Fahrenheit or below, by circulatory collapse with blood pressure below 80 systolic, dry mucous membranes and skin, soft eyeballs, and by hemorrhagic vomitus or gastric contents. Air hunger, though slight but definite at first, increases to a maximum and toward the end gives way to shallow respiration.

The size of the first dose of insulin in coma depends upon the doctor's estimation of the probable number of hours the patient would live without insulin. If the patient's expectation of life is 24 hours, one would inject 20 units and repeat every hour until clinical improvement and sugar in the urine or blood is approaching normal. If the patient's expectation is 12 hours, one would inject 40 units and repeat the dose in the same manner, changing the quantity to 20 units as the state of the patient warrants. If the expectation is only 6 hours, one would inject 40 units every thirty minutes until improvement is manifest. Finally, in a case in extremis we should now give 40 units of insulin every fifteen minutes. No patient at the New England Deaconess Hospital should come within two hours of death from coma without having received at least 150 units of insulin in the preceding hour.

## THE DISTRICT BRANCH MEETINGS

The months go by with a swish, and we are reminded of most agreeable experiences as we attended the meetings of the District Branches last Fall. We are anxious to repeat our visits to the Branches.

The District Branches are gold mines of usefulness whose riches have scarcely been touched. The theory on which they are founded is that of groups which have a common interest, and are readily accessible to one another. The present Districts do not meet those conditions.

The present District Branches comprise the old judicial districts, and some extend across the State, defying natural boundaries and routes of travel.

The Districts are also too large. We notice that other state societies make their Branches smaller. Michigan has 14 Branches divided according to congressional districts, Illinois has 9 District Branches.

The present House of Delegates has authorized the redistricting of the State. A wise method of forming the new districts is to give consideration to the natural grouping of the physicians, which are determined largely by geographical conditions. This is the plan that has been followed by the State Department of Health in the assignment of its fifteen District State Health Officers to their districts. If the District Branches were identical with the health officer districts, each branch president would find his work sufficient to occupy all the time he should be expected to give to it.

The District Branches which held the best meetings last Fall were those whose grouping was compact and according to natural routes of travel. Smaller districts, formed on these lines, will promote better Branch meetings, and a more effective system of advice and supervision for the county societies.

F O

## MEDICAL WRITINGS

The subject of graduate education has many phases. One of the oldest and most efficient means of educating physicians is that by means of articles in medical periodicals. Another is that of clinical demonstrations on actual cases. Either method is incomplete without the other—and an efficient system of graduate instruction in medicine will utilize both methods.

It is the peculiar work of the medical editor to choose articles which will enable physicians to practice clinical medicine in the ready manner that is exhibited by the expert demonstrator before his class. We believe that reports of actual teaching clinics are among the most useful and popular articles in our State Journal.

What is the mental attitude of a clinical teacher before his class? It is exactly the same as that of a physician in the presence of his patient whom he is seeing for the first time. On the one hand the teacher has a great number of items of knowledge classified, systematized, and filed away in his brain for ready use. This is the text book or medical article equipment of the physician—the tools with which he works. On the other hand there is a sick person on whom the physician will apply some items of his mental equipment.

The expert teacher does not use every bit of mental equipment that he happens to possess on every patient, any more than a modest surgeon lays out all his instruments for every operation. The teacher stands before his audience and thinks out loud. He reveals the mental processes by which he reaches a conclusion. Those processes may be brief and direct in certain cases, or lengthy and complicated in others, but in either event the teacher reveals the items of knowledge which he applies to the particular sick person, and also demonstrates how he uses those items.

The ideal clinical lecture will consist of two parts. First, there will be a general text book description of the condition to be demonstrated. This will give a picture of the ideal or standard case, which of course seldom exists.

Secondly, the teacher will point out the actual

picture which the sick person presents to his mind, and will compare that picture with the ideal or text book description of the sickness. This is the most practical method of teaching the practice of medicine.

What class of cases are most interesting to doctors? Physicians are most interested in the class which they see the most often—the common lesions of the heart, lungs, kidneys, and stomach. Advances in the methods of diagnosis and treatment are continually being made, and in the course of five years a general practitioner is likely to be behind the times in most subjects.

Dr. Gordon and his colleagues on the committee on Public Health and Medical Education, are planning to make medical study easy for the members of the State Society. The plan is to systematize instruction, so that a doctor can get a broad view of a medical subject with a minimum of effort. This means that articles of an elementary nature must be prepared, and that clinical teachers must be provided for classes of general practitioners.

There is a ready test for the popularity and practicality of a subject. We have made it our practice to attend as many clinical demonstrations as possible, and to take notes and make abstracts of the teachers' remarks. If the teacher was interesting and practical, we always have had impatient requests from his hearers to know when we are going to publish the abstract.

We believe that an elementary text book article on some common disease, ending with clinical reports of actual cases, is the most useful form of paper that we can publish.

We have now and then found most excellent clinical teachers who object to the publication of their remarks. The ground of their objection is usually that their remarks are too simple and incomplete for publication. Our reply is that if they interest an audience of listeners, they will also interest an audience of readers.

We have treated this same subject editorially on page 659 of our April 17 issue. F O

## MEDICAL PRACTICE ACT

The Special Committee of Seven appointed by the President on the authorization of the House of Delegates, to prepare a Medical Practice Act for introduction in the Legislature during the session of 1926, has held fortnightly meetings all

through the Summer, and has outlined a comprehensive bill. The magnitude of the task and the necessity of extensive investigations have precluded the completion of the work by September 1st, but a report in the near future is assured.

# LEGAL

By GEORGE W. WHITESIDE, Esq  
Counsel, Medical Society of the State of New York

## A TRIAL BY JURY SHALL REMAIN INVIOLETE FOREVER

*"Gentlemen of the Jury Take the case and do the fine fair thing with it You must not allow sympathy, you must not allow prejudice to influence you and I am sure you will not Whenever anybody has suffered pain we are bound to be sympathetic, but we are deciding a case on the law, not on sympathy, not on prejudice Take it and do the fine fair thing with it and thereby we will be vindicating that system of justice which we are so proud of and which, of course, really needs no vindication"*

Thus spoke the judge after three weeks of weary trial of three doctors as he committed to twelve men, good and true, the case for decision. Was the diagnosis based on a proper scientific examination? Was the operation which was performed justified? Were the doctors responsible for the infection appearing after the operation, for the long suffering and injury claimed by the plaintiff to have resulted therefrom? Were the doctors responsible for the disabilities suffered by the plaintiff some years later? Should they be condemned and heavy damages assessed against them? The pathologist, bacteriologist, the surgeon, the medical men on both sides of the case had given voluminous testimony and the time had come for the twelve laymen to say what they thought a negative culture, after twenty-four hours' incubation, signified, what the leucocyte count indicated, what story the various microscopic and chemical urine tests told, whence came the bacilli and bacteria in the plaintiff's urine, what diagnosis, operation and treatment they thought was proper in the case. These twelve jurors became the final judges of the scientific questions with which the most expert of specialists had struggled and were, by their decision, to determine whether the reputation for scientific knowledge, skill and care of these defendant doctors, built up by years of self sacrifice study and devotion to their profession, was to be destroyed by a decision that they were unfit, unqualified or careless in the treatment of the plaintiff. These jurors were men whose training, education and experience were all foreign to the practice of medicine. A grocer, a horticulturist, an architect, an engineer, a barber, an accountant, a bank clerk, a salesman, a small town merchant and several business men comprised the jury to whose tender mercies these important issues were committed. Whether the case be one for goods sold, debt, or one based on science, evolution or the

books of Genesis, a trial by jury "shall remain inviolate forever"

Had not these men at the beginning of the trial raised their right hands and sworn they would well and truly try the issue joined between the plaintiff and the defendants and a just verdict render according to the evidence, and had not the judge with patience and learning for about an hour and a half charged the jury, elucidating to them the facts of the case as given on both sides and the law to be applied to those facts, finally saying "that the right of the plaintiff to recover in this case necessarily depends upon medical evidence, that the plaintiff may not recover merely on the evidence of laymen—this is the law of this state, whatever it may be in other states—nor by the jurors considering because of their own knowledge or experience

In this connection the plaintiff claims that upon the credible medical and other evidence in this case he has established that the diagnosis and treatment of himself was not characterized by that skill and care which the law requires and that injury because of that resulted to him, he claims this upon evidence including the testimony of medical experts

The defendants, on the other hand, claim that on the whole case they exercised the care and skill required by law and further, that any result, even if not good, is not shown to be attributable or traceable to what they or any one or more of the defendants did, that what they or any one of them did is not shown to be a competent producing or proximate cause of the plaintiff's claimed injury"

The jury retires from the hot courtroom behind the closed door where the evidence is to be discussed. The principals in the tragedy await patiently and apprehensively for the knock on the door from within that signalizes that the jury have agreed. A half hour passes—time drags on until an hour has elapsed. Will disagreement of the jury make necessary a retrial for another three or four weeks of the whole case? The second hour passes. All that can be heard as the night wears on in the courtroom is the dim sound of voices from behind the closed door of the juryroom. Three hours—the question so vital to these doctors remains unanswered. Within the next quarter of an hour a rapping is heard. The whispers about the courtroom of those who have lingered are plainly heard, "they have agreed." Counsel studies the faces of the jury as they pass into the courtroom, hopeful that from the

expression of the eye he may glean some faint hope that his clients' fate has been justly decided. The court clerk who hundreds and hundreds of times during the past years has droned out the same question, rises and says, "Gentlemen of the jury, have you agreed upon a verdict?" responds the foreman, "We have." "How find you?" The foreman seems conscious that all eyes are boring into his trying to read the answer before his lips move—"We find a verdict in favor of—the defendants." Counsel on each side, who had waged bitter warfare for three weeks, marshalling against each other their scientific battalions, mowing down scientific fallacies and building up defenses of impregnable truth, who have summed up with all the scathing sarcasm and contempt that each command, exchange felicitations. The doctor defendants hardly realize that the strain is over and they have won as they slowly recover from the shuddering thought that science, under

the constitution, is ultimately at the mercy of the lay jury's verdict. The case is over. Counsel returns to his office to learn that other cases for other doctors are crowding their way up to the top of the calendar, ready to be sent out for trial. Then, again the drama in another case will be enacted for a day, two days or more, on a different stage with another cast, which will be in most respects a repetition of that upon which the final asbestos curtain was lowered the night before.

What will the next jury composed of salesmen, merchants, farmers, grocers, machinists, engineers, trolley car conductors, bank presidents, clerks, investment brokers and professors do with the case left to their decision, and the next, and the next? For Article 1 of the Constitution says, "*The trial by jury in all cases in which it has been heretofore used shall remain inviolate forever*"

### INJURED ANKLE—SUBSEQUENT INFECTION

In this action it was charged that the defendant as a physician, about the middle of December, was engaged to attend the plaintiff for an injury to her left foot and that he failed to render proper treatment and care for a period of about two weeks after his engagement. It was claimed that he applied a plaster cast to the ankle and foot at a time when the same was infected and that the infection was thereby increased and caused an abscess to form, resulting in the spread of the infection. That about two weeks thereafter he operated upon the ankle at which time he failed properly to cleanse, disinfect and drain the wound, with the result that the plaintiff's foot and ankle and leg up to the knee became poisoned and infected. That the plaintiff suffered for a period of ten weeks, during which time it was necessary for her to be under the care of another physician. That she was prevented from attending her employment and confined to bed for about eight weeks.

From the doctor's records it appeared that at the time he first attended the plaintiff he found that she had slipped and fallen, sustaining an injury to the left ankle. He prescribed an opium and lead wash. At this time no infection was discovered by the defendant. The patient was told to remain in bed and that the doctor would return in two days and for her to apply the prescription in the meantime. When he returned two days thereafter he found the patient in bed, examined the foot

and ankle and noted a subsidence of the swelling. There was no redness or infection in the region of the ankle at this time. The ankle was then strapped with adhesive tape and the patient was advised to remain in bed for three days and to advise the defendant physician at that time of the condition of the foot.

Nothing was heard from the patient by the doctor until ten days thereafter, when the patient was up and about and had failed to follow the instructions which had been given her. The plaintiff had also been going to her work daily. She complained of pain in the ankle and upon removal of the adhesive plaster the skin on the margin of the plaster was found infected. The wound was cleansed and an iodoform gauze drain placed in the wound, the ankle bandaged and the plaintiff advised to remain in bed. On the following day the doctor called, examined the foot, dressed the wound and rebandaged it. For three successive days he called daily, examining and dressing the foot each time, and the foot during this time showing improvement. At that time he advised the patient to come to his office upon the following day. Nothing further was heard from the patient until the institution of this action.

The matter finally came on for trial and at the close of the plaintiff's case was dismissed upon the merits by the trial court, thus favorably terminating the action in favor of the defendant physician.

## State Department of Health

### CASE OF TETANUS FROM AN UNUSUAL INJURY

According to a report, by the attending physician, Dr Joseph G Patiky, of Huntington, Long Island, the patient, a boy two years old, was playing in the yard of his home when he fell down and injured his eye. At that time, apparently, there was no foreign body in the eye. On the following day, when Dr Patiky first saw the case, the lids of the injured eye were markedly swollen, with a very free discharge of pus. The child was referred to an eye specialist the same day who was unable to open the lids sufficiently to see the eyeball. On the next day the swelling and discharge of pus had somewhat subsided and the child's mother while bathing the eye removed a piece of wood about one-half inch long and about the thickness of a match. Dr Patiky again examined the child and found the eyeball was uninjured, but observed a hole in the upper lid where the wood had been imbedded. At

this time infection no longer seemed to be present.

On the following day, three days after the date of injury, the patient developed slight twitching of his face and arm on the injured side. He was immediately given 10,000 units of tetanus antitoxin subcutaneously and intramuscularly and two hours later 20,000 units intraspinaly. The muscular twitching, however, became worse and in twenty-four hours the child had tetanic seizures of the entire body. Twenty thousand units of antitoxin were again administered intraspinaly and the same amount after twenty-four hours. In spite of the treatment the temperature reached 106.5 and the patient died a few hours later.

This case is deemed worthy of note because of the unusual type of injury and the very short incubation period.

### DEATH FROM AMOEBIC DYSENTERY COMPLICATED BY ABSCESS

Following a request of the Division of Communicable Diseases, a report was recently received from the Buffalo General Hospital, giving the history and findings in the case of a patient whose death was reported to be due to "amoebic abscess of liver and lung—parenchymatous degeneration of viscera."

According to the history received, this patient suffered with acute diarrhea lasting about two weeks, in September, 1924. It was noticed that there was blood in his stools throughout the attack. In November he developed shortness of breath upon exertion. His legs and ankles started to swell and he was admitted to the emergency hospital on November 2, where he remained until the middle of January. During this time he lost forty pounds. In December he was troubled with a cough and profuse yellow expectoration. He was admitted to the General Hospital on February 28. He had spasmodic coughing but apparently no pain. Breath sounds were diminished over bases, more so over the right base and axilla. Legs and ankles were oedematous. No

amoebae were found in several examinations of feces. X-ray examination indicated that there was an elevation of the right diaphragm, apparently produced by something crowding up from below, e. g., echinococcus or abscess. On March 11 the patient raised a large amount of dark brown sputum. It contained many pus cells. Clinically, there was evidence of considerable fluid in the right chest. Patient died on March 25.

Autopsy showed healed ulcers in the colon. Two large abscesses were found in the right lobe of the liver with perforation through the diaphragm into the adherent upper ('1') lobe of the right lung with the formation of an irregular multi-locular abscess occupying the greater half of the lobe, and showing perforation into the bronchus of the upper lobe. Also there was right-sided pleurisy, purulent bronchitis with numerous foci of lobular pneumonia, moderate swelling and softening of the spleen, degeneration of the heart muscle, liver and kidneys, oedema and anaemia of brain. Amoebae were isolated from specimens following autopsy.

ries, and the result is that the city of Watertown has milk of an unusually high standard

*Hospitals*—Jefferson County has three general hospitals and a County Tuberculosis Sanatorium, as follows

City Hospital, Watertown	100 beds
Mercy Hospital, Watertown	90 beds
General Hospital, Theresa	20 beds
County Tuberculosis, Watertown	50 beds
Total	260 beds

The county has 3.25 hospital beds for every thousand of population. The hospitals are usually full, and Mercy Hospital is adding 90 beds to its equipment. The village of Carthage, the southeastern corner of the county, is about to start its own hospital, and the local hospital Theresa takes care of emergency cases in the northern section of the county.

The City Hospital maintains a high standard, in accordance with that of the American College of Surgeons. It maintains an excellent laboratory and employs a history clerk. Both it and the Mercy Hospital conduct training schools for nurses.

*Clinics*—The outpatient care of the sick is done in clinics held in the Memorial Health Building in Watertown, which was built with funds left over from the War Chest. It provides space for clinics in pediatrics, pre-natal, tuberculosis, throat work and dentistry, and is the headquarters for the public health nurses and the Red Cross workers.

A venereal disease clinic is about to be established in the Mercy Hospital.

*Departments of Health*—The official public health work of Jefferson County is in charge of health officers who serve 35 districts. Each health officer outside of Watertown serves an average of about 2,200 people.

The health officers of Jefferson County are well equipped for their work. Seventy per cent of the health officers have taken special courses to fit themselves for their work (see this Journal, August, 1925, page 877).

Seventy-five per cent of the health officers are members of the County Society.

Forty-five per cent of the physicians outside of Watertown are health officers.

The tuberculosis work of Jefferson County centers in the County Sanatorium, which is located just outside of Watertown. There is also a Lay Tuberculosis Committee. The leaders in the County Medical Society are planning for an enlarged scope of tuberculosis activity of the county which shall include a full-time superintendent of the hospital, and teaching clinics for the instruction of the physicians of the county.

Jefferson County has no official public health laboratory, but emergency examinations of cul-

tures are made in the City Hospital of Watertown. The county has 10 public health nurses.

*Medical Publicity*—The Jefferson County Medical Society has a committee on publicity which has made serious attempts to do publicity work through the daily press. The newspapers are well disposed toward the physicians, and the two dailies of Watertown are willing to co-operate with the physicians. The publicity committee of the County Society plans to make publicity of the meetings and activities of the Society through the newspapers.

*Impressions*—The physicians of Jefferson County are united and progressive to an unusual degree. The success of their organizations is due to a considerable extent to the peculiarly favorable geographic conditions. The city of Watertown is the natural center of the county in nearly every respect, and the whole county medically and otherwise, is a suburb of the city. Added to this is a progressiveness and a spirit of co-operation on the part of the physicians of both the urban and the rural sections. The doctors of Jefferson County are setting an example for the rest of the State.

#### LEWIS COUNTY

Lewis County adjoins Jefferson on the east and south. Its medical conditions are largely dependent on those of Jefferson County. The physicians of Lewis County associate themselves closely with those of Jefferson County, and attend the meetings which are held in Watertown. This close association is due to geographic conditions.

Lewis County has an area of 1,270 square miles, and a population of 23,704, according to the 1920 census. The population is about 1,000 less than it was in 1850, and 7,000 less than in 1880, when the population was at its peak.

Lewis County occupies the broad valley of the Black River which flows north through the center of the county, and passes through Watertown. Travel is easy down the river valley, but is difficult over the mountains on the east and west.

The villages of Lewis County are located on the Black River. The largest is Lowville, with 3,127 population, which is increasing.

There are 20 doctors practicing in Lewis County, or one doctor to every 1,200 people. They are located in 11 centers, mostly along the river valley. The Lewis County Medical Society has 15 members, a large proportion of whom also attend the medical meetings in Watertown.

There are 10 health officers in Lewis County, all of whom are members of the County Society. Six of the health officers have taken special courses of instruction for health officers.

The physicians of Lewis County are progressive and active, and are interested in graduate medical education.

## DISTRICT BRANCHES

### ANNUAL MEETINGS FOR 1925

First District Branch—Wednesday, October 14, Poughkeepsie

Second District Branch—Tuesday, October 13, Hempstead

Third District Branch—Friday and Saturday, September 25 and 26, Haines Falls

Fourth District Branch—Thursday, October 8, Amsterdam

Fifth District Branch—Friday, October 9, Marcy

Sixth District Branch—Tuesday, October 6, Ithaca

Seventh District Branch—Thursday, September 24, Auburn

Eighth District Branch—Wednesday, October 7, Buffalo

## THIRD DISTRICT BRANCH

ANNUAL MEETING, TWILIGHT PARK, HAINES FALLS, FRIDAY AND SATURDAY, SEPTEMBER 25TH AND 26TH, 1925

The first day of the meeting will be devoted to the scientific and business sessions of the Branch

The second day of the meeting will be devoted to sports of various kinds

Special rates are offered by the management to those who wish to spend the week-end at the Park.

Special attractions will be provided for the ladies

Come early, stay late, bring your wives and sweethearts and enjoy yourself

### PROGRAM

Friday, September 25th, 1925

10 A M, Daylight Saving Time

Address of Welcome—Lyle B Honeyford, M D, President Greene County Medical Society

President's Address—Charles P McCabe, M D, Greenville, President Third District Branch

### SYMPOSIUM

Lesions of the Stomach

Diagnosis—Illustrated with lantern slides, Charles Gordon Heyd, M D, New York

Medical Treatment—Anthony Bassler, M D, New York City

Surgical Treatment—Charles H Peck, M D, New York City

Luncheon 1 30

Afternoon Session

### Business Session

Reports of the Chairmen of the Committees on Medical Education, Public Health, Nursing Situation, Membership, County Society Programs

Address—Nathan B Van Etten, M D, New York City, President, Medical Society of the State of New York

Address—Daniel S Dougherty, M D, New York City, Secretary, Medical Society of the State of New York

Address—The Functions of a District Branch, Joseph S Lawrence, M D, Executive Officer, Medical Society of the State of New York

Scientific Paper—Some Neurological Problems, Nelson K Fromm, M D, Albany

Address—Col George F Chandler, M D, Kingston, Member Committee on Graduate Medical Extension Instruction

Dinner, 6 30 P M

Evening Session 8 30 P M

Moving Picture—Lesions of the Stomach (Furnished by the Medical Society of the State of New York)

Dancing—9 30 P M

SATURDAY, SEPTEMBER 26, 1925

Saturday, September 26th, will be given over to sports of various kinds. The management of the hotel offers cups for the winners in the various events. Special arrangements have been made for the entertainment of the ladies

## FOURTH DISTRICT BRANCH

ANNUAL MEETING, AMSTERDAM, THURSDAY, OCTOBER 8, 1925

Address of Welcome—Horace M Hicks, M D ,  
President, Fourth District Branch

Address—Nathan B Van Etten M D , Presi-  
dent Medical Society of the State of New York

Address—Daniel S Dougherty, M D , Secre-  
tary, Medical Society of the State of New York

Address—Joseph S Lawrence, M D , Execu-  
tive Officer, Medical Society of the State of  
New York

"Details of How the Medical Society of the  
County of Montgomery Will Provide Post-  
Graduate Courses for the Members of the County  
Society," Charles Stover, M D , Amsterdam

"Details of the Use of the Improved Barton  
Obstetric Forceps," William E Caldwell, M D ,  
New York City

"Physiognomy and Its Relation to Diagnosis,"  
George Draper, M D , New York City

County Laboratory Exhibit of pathological  
specimens, including interesting slides Dr Dick-  
son of the laboratory will speak in regard to this  
demonstration

### EVENING SESSION

(Open to the Public)

Films on Tuberculosis, with local and outside  
speakers

# NEWS NOTES

## THE FLOATING HOSPITAL OF ST JOHN'S GUILD

We recently spent a pleasant day on the Floating Hospital of St John's Guild, whose headquarters are at 52 Vanderbilt Avenue, New York City, and observed the operation of one of New York City's most interesting institutions. We started from the foot of East 26th Street at 9 o'clock with 200 women, 680 children, and 88 babies on board, and sailed to Sandy Hook and back. The boat was filled to only half its capacity, for a slight collision, in which no one was hurt, had been magnified in the dailies, and many East Side mothers were afraid to go on the boat. Enterprising reporters had even been caught tying towels around the heads of the children and posing them for photographs of the "injured." Such are some of the difficulties with which the well-doers must contend in the busy city.

The Floating Hospital was organized in 1866 to provide a cool retreat for sick babies in the days when summer complaints were ascribed to the heat principally. The boat now carries a fully equipped hospital for 32 children, with two internes and a full equipment of nurses and dietitians. The beds contained 20 severely sick children on the day of our visit.

The boat also takes on board mothers and children without much restriction as to age, and none as to social condition. The doctors inspect the

children for head lice and other contagious conditions, as the passengers come aboard, and those who are found to be affected are isolated until they can be treated. Salt water baths are available for all, and milk and sandwiches are distributed. A supervisor of plays is employed, and half of the lower deck is the stage for games during the entire day.

The backs of the benches are provided with hammocks in which the babies swing and sleep under the eyes of their mothers, who often stretch themselves on the benches for a day of relaxation.

One of the newest and most interesting phases of the Floating Hospital was the educational work which is carried on by the Health Teacher, Miss Jessie Forshaw. We were particularly interested in the work of Miss Forshaw because we have tried to devise methods of teaching medical facts to laymen, and we believe that the Floating Hospital affords an effective means of reaching mothers. The talks are based on actual cases which she observes, the mothers are personally interested in what she says, and there is leisure time to absorb and discuss the teacher's words. We are printing Miss Forshaw's own description of her work.

F O

## HEALTH TEACHING ON THE FLOATING HOSPITAL

By JESSIE FORSHAW,

Health Teacher

The "Floating Hospital," which belongs to St John's Guild, a philanthropic organization, sails from New York piers daily throughout two months of the summer. It carries an average group of 600 children and 140 babies, and 260 mothers accompanying them. For the children, a recreational program is provided, to combine physical exercise with a certain amount of health education, with the mothers a direct program of instruction in matters of health is attempted by the health teacher.

Instead of lecturing formally to assembled groups, the aim of the health teacher is to effect a daily personal contact with each mother in a free and friendly manner. While doing this, opportunity is easily afforded for the observation of faulty or improper child hygiene. Such matters as physical defects, incorrect methods of feeding, the cultivation of improper habits, and so forth, are brought to light. The situation is exceptionally well adapted for such work, as the

mothers and children are on the boat for the whole day, while many take all the trips during the summer. Another factor which favors the health teacher is the relaxed and receptive mood of the mothers, due to their freedom from household worries. There are no distracting stimuli with which to contend, such as a pot burning dry, or a tub of clothes to be washed.

### A TYPICAL DAY

A description of a few of the observations made during the day will serve to illustrate the method of attack, and the kind of instruction which is given.

I find several two- or three-year-old children drinking from nursing bottles. This introduces a talk to their mothers about habit formation, and the effect of diet on the nutrition and general development of the child. Some mother, by way of defending herself, will say that her child is "skinny," has no appetite, and will not take any-

thing except from the bottle I take advantage of her admission that the bottle is the cause of the child's trouble, and explain in simple and intelligible language how its appetite may have been satisfied, whereas its nutritional needs have not. During this explanation the attention of fifteen or twenty other mothers has been attracted, and some of these have undoubtedly taken to themselves something of benefit from the instruction.

The mother in the next seat will ask me to look at her boy. He is "skinny," she says. Also that at school he was told he had tonsils, which she does not believe. And will I tell her? Yes, he has diseased tonsils. I show them to her—enlarged, cryptic, and marked with pus. I explain to her that this may be one of the reasons why her child is "skinny." I then equip her with a note to a tonsil clinic, and I feel certain that she will have the condition remedied. She will do this because she has been directly convinced that the child has diseased tonsils, and because I have taken the time to explain the possible effects of neglect. Often mothers in the seats near by have been listening, and there will be competition among them as they try to get my attention riveted on their children. Health teaching is thus immensely simplified. The attention of the mothers has been aroused. They want to know. The rest is easy.

I find a mother screeching at her child who is in a well defined temper tantrum. It takes some time to recall the mother to a reasoning state of mind, but after that a quiet little talk is in order, the child having been sent in the meantime to play with others. I try to impress upon those in that particular corner that motherhood is more than the mere feeding and clothing of a child. It is also the training of a child to make adjustments even to its own small environment. Mothers are much too prone to keep their young ones dependent, instead of encouraging resourcefulness in them.

The next problem may be the much hackneyed "pacifier" question. There is still much to be accomplished in this regard, in spite of the great good that health workers have already done. In this instance I choose a young mother to speak to, because I know I will get a better reaction from the surrounding group. One can say a great deal to a young mother, much that others will drink in without feeling that their "divine right of instinctive motherhood" has been slandered. Surprise creeps over their faces as I tell them that God intended babies to cry in reasonable amount, that it is thus they learn to gurgle and later to talk, and that they need the exercise of crying to encourage lung and abdominal development. It is like a new gospel to these women, and most of them find an unexpected relief in it.

In a seat not far away I find a boy of about

fourteen years of age huddled close to his mother. I ask why he does not play with the other boys, and soon discover that he is one whose personality requires careful handling if he is to be saved from succumbing to the dangers of adolescence. The necessary teaching in this case is hard to give the average layman, but something needs to be done. The most practical act is to take him to the playroom, and have the play directors help him mix with the other boys. The mother will refuse to let him go, pleading that "he is afraid," and this leads on to a discussion of healthy play, and the abuse of the instinct of fear. Frightening a child in order to secure obedience shows only poor management, and is a crime against him. Points to be stressed are the need of play and recreation, the danger of over-fatigue from too much activity, and the importance of a regular and reasonable bedtime.

Here is a mother who has her baby overdressed. This gives occasion for a much-needed talk on the proper clothing of the baby. During the summer months, especially, the poor things seem to suffer from a superabundance of motherly affection along this line.

In the midst of all this a mother is discovered giving her three-year-old a huge dill pickle, which the latter seems to relish immensely, clasping it much as one would a banana. Ten years from now medical science may discover that dill pickles contain some very necessary elements of nutrition, but for the present they are taboo. This violation of diet standards provides another opportunity to explain the importance of food for the growing child and also to suggest the kind of diet suitable to such a child, together with the need for attractive and regular preparation of meals.

I find a child with whooping cough, and try first to impress upon the mother that she has violated a moral responsibility by bringing her child in contact with others. I can then explain the modern conception of the communication of diseases, illustrating the principle with the concrete situation before me.

These instances show what can be done in the way of instructing women along health lines, and how it may be accomplished in the direct way. The repetition which occurs when different mothers require the same sort of information, and which would be avoided by the lecture method, is more than compensated for by the strength of the impression made through the direct personal talk. No one is allowed to think that the instruction is theoretical or academic. The audience has always a concrete case before it, and one which bears a close personal interest for at least one member of the group. In this way the "project method" is put into practice, and the positive results are indeed gratifying.

## LIVINGSTON COUNTY MEDICAL SOCIETY

A regular meeting of the Livingston County Medical Society was held at the Craig Colony, Sonyea, N Y, on May 5th, 1925. It has become an established custom for the Society to hold its regular spring meeting at this institution as guests of the Medical Superintendent, Dr William T Shanahan, and his staff.

Following an excellent luncheon at 1 P M, the Society was called to order by President Harold A Patterson. The scientific program preceded the business meeting and was as follows:

"The Treatment of Cardiac Decompensation," by Dr Edward W Jackson, Rochester. Dr Jackson's paper was a valuable one to the general practitioner, explaining as he did, the newer methods of treatment of cardiac conditions. The free discussions that followed emphasized the interest with which the members had listened to his presentation.

"The Evaluation of Symptoms," by Dr George Eckel, Buffalo. Dr Eckel's talk was of immense practical value. He took up some of the more common symptoms with a view of differential diagnosis and cited cases to illustrate the

various points made. He laid particular stress on the part played by focal infections in the production of vague symptomatology.

The Society was especially honored by the presence of the President of the Medical Society of the State of New York, Dr Owen E Jones, who next addressed the Society with an eloquent plea for "Preventive Medicine." Dr Joseph Lawrence, Executive Officer of the State Society, gave an outline of the work being carried on by the State Society and of its plans for the future. His talk convinced all present of the necessity for the increase in the State dues and the need for close co-operation between the State and County Societies.

The usual routine business session followed which included the reading of the minutes of the last meeting and reports of committees. The Society received the application of Dr Philip A. Palsano of Mt Morris and duly elected him to its membership. The matter of the revision of the fee bill was again voted to be laid on the table until next meeting. Twenty-three members and nine guests were present.

## KEUKA LAKE MEDICAL SOCIETY

The twenty-sixth annual meeting of the Lake Keuka Medical and Surgical Association was held on July 9th and 10th in the Keuka Hotel, Keuka, Steuben County. The Society combines science with pleasure, and its members and their wives get together on Keuka Lake for a two-day outing on the Thursday and Friday nearest the full moon of July.

The Association has no formal membership list, but about 250 physicians from most of the counties of Central New York come together spontaneously and elect a president and a secretary and pay two dollars apiece toward the expenses of the meeting. We received from Dr John A Hatch, of Penn Yan, Secretary of the organization, a program which announced the meeting as the "Snappiest Surgical and Meatiest Medical Meeting in New York State for 1925."

"Program Points," contained in the announcement are as follows:

Douglas P Arnold, M D, Buffalo Children's Hospital—"Diarrhea in Children," lantern slides

Oswald S Lowsley, M D, F A C S, Uro-

logist, New York City Hospital—"Regional Anesthesia in Kidney Surgery," lantern slides

Samuel Calvin Smith, M D, Cardiologist, Philadelphia—"Cardiac Irregularities"

Charles Gordon Heyd, M D, F A C S, Professor of Surgery, New York Post Graduate Hospital—"Differential Diagnosis of the Right Upper Abdomen"

Charles Franklin Hoover, M D, Professor in Medicine at Western Reserve, attending Lakeside Hospital, Cleveland

William Edgar Caldwell, M D, F A C S, Visiting Obstetrician, Sloan Maternity Hospital, New York City

Ethan Flagg Butler, M D, F A C S, Chest Surgeon, Packer Hospital Clinic, Sayre—"Lung Abscess," lantern slides

Homer L Samson, Roentgenologist, Saranac Lake—"X-Ray Diagnosis and Prognosis of Pulmonary Tuberculosis," lantern slides and films

The Keuka Lake Medical Association is a great educational and social force in Central New York, and we hope we may be able to attend its meeting next year and report it in full.

F O

# THE DAILY PRESS

## EDITORIAL EXPLANATION

We have tried an experiment. We took a week's clippings and gave them to a theological student and a medical student, each of whom had completed two years of professional training.

These two men read the clippings carefully, and each wrote his impressions without consulting the other. We are pleased to print their opinions, especially since they confirmed our own. F O

## A LAYMAN'S REVIEW

A great number of medical clippings from the daily press were recently put into my hands, and my lay opinion was asked as to their popular interest and value. The general purpose of these articles is not only to arouse the interest of the people, but also to educate them, not only to advertise medical activities throughout the State, but also to arouse a sympathetic interest in these activities, which will lead to a public benefit.

These clippings covering the month of July seemed to fail utterly in their main purpose—that of arousing interest. They seemed to be successful only in so far as they filled up newspaper space. A very large percentage failed even to interest.

We noted large striking headlines, such as, "Mayors of State Co-operating for Public's Health. Conference of Officials Has Secured United Action on Cities' Problems," under which is a full column containing practically nothing of public interest except perhaps a statistical and chronological history of the five preceding meetings, and absolutely nothing informative about the problems of health which confronted the city, which problems were advertised so glaringly in the headlines. Another large percentage dealt with statistics setting forth the increase of alcoholism and the decrease of infant mortality. These, though they have some news value, seem to have little that interests the general public, and certainly very little that bears on the health or education of the individual reader.

A large class of people seem to be affected by the popular advertisement. They turn for their authority to the wise sayings of our popular heroes. Henry Ford, it is claimed, set forth the novel idea, "The fate of the world lies in food." The article goes on to state "This is not the statement of a fanatic, but of one of the biggest business men of the world, and can be substantiated by uncontrovertible proof." The article then expounds at length upon the care we take of our animals and the small percentage of sicknesses in their life history, ending with the rhetorical appeals "Why should intelligent people eat simply to glorify a depraved appetite? Is it possible for man to improve upon God's plan?"

The author invites any who are interested to talk the matter over with him. Unless he is prefacing a series of articles, it seems to me that it would be helpful if he set forth in a simple way the fund of knowledge upon this subject or food which he proposes to talk about. As he is an official of the educational council of a lay organization, his authority would be a good one, and anything he might have to say in a less general way would be read with interest and benefit.

(EDITORIAL NOTE. The reviewer was deceived by this article, as its author seemed to intend every reader should be, for he represents a commercial organization.)

The greatest number of clippings show all the earmarks of coming through the unaided efforts of the reporter of that department of the paper. Most of them show an optimism and a hopefulness that is delightful and which undoubtedly go far to cheering up our day, but like the rest, they seem to be lacking in interest and effectiveness. Under the headline "Health Talks," it says "What are the purposes and aims of health education? To instruct children and youth so that they may conserve and improve their own health, to establish in them the habits and principles of living which throughout their school life, and in later years, will assure abundant vigor and vitality which provide the basis for the greatest possible happiness and service in personal, family and community life, to influence parents and other adults, through the health education program for children, to better habits and attitudes so that the school may become an effective agency for the promotion of the social aspects of health education in the family and community, as well as in the school itself, to improve the individual and community life of the future, to insure a better generation and a still better third generation, a healthier and better nation and race" (*Tarrytown News*, July 15). Many writers follow this hopeful editorial style under headings relating to public health, yet it is woefully lacking in anything of special interest or information.

We are impressed and interested by the numerous clippings relating to clinics of one sort or

another which, because of number of clippings and because of the many societies represented, we judge are being held frequently and generally. We are led to believe the public can be helped a great deal in this way, and that information in regard to this source of aid is much needed.

The article which interested me most related to scabies. It gave the history, symptoms, and cure of the disease in a simple, direct way. It had the professional tone of authority, and led me to feel that I was learning something which might at some time serve a purpose. Now, we have never had scabies, and do not know of any one that ever had scabies. In fact we are not sure we ever heard of it before, and so the interest we took in the article could hardly have been a personal one. The interest was due to the nature of the article. To many the newspaper is a primary source of certain kinds of information, and real

information is usually appreciated. Health is a subject in which the general public takes a real interest, because to most of us it represents a goal not quite attained. The people generally are able to take a far more intelligent interest in things medical than is credited to them by those who have had a professional training, if one can judge at all by these sample clippings. We believe that the people would understand and appreciate a greater number of items of a scientific nature.

Professional education through the press undoubtedly has a large field of opportunity, but its aims so hopefully set forth can only be realized when more professional time and interest is given to the press articles by those physicians who are able to write them.

ALBERT LEE KLAER, A B

### A MEDICAL STUDENT'S OPINION

The daily newspapers carry many articles in relation to health, and among the most conspicuous are the syndicated health talks. They are commonly a regular feature. The fact that these articles appear regularly and usually on a certain page, practically guarantees a host of readers. Therefore, they have much obvious potential value as a medium for educating the people on health matters. The popular style in which such articles are presented is commendable, but in reverting to conversational English, something of inaccuracy may develop. The deplorable thing concerning them is that they are often carelessly written. Not only can a medical student find inaccuracies in details, but he can also perceive instances where, due to carelessness of the author, the paragraphs lead one to an erroneous conclusion. These syndicated articles, unless of the best, can very easily result in detriment. The fact that these articles so often do not inspire the confidence of medical students leads one to doubt their value, for, if a medical student is unable to derive benefit from them, how many laymen are benefited by them?

The remaining health articles in the daily press appear purely because of their positive news value. They are the products of the reporter's sincere efforts and are intended to be what he believes is a readable news story. He must rely on his own fund of knowledge to supply the human interest to the bare skeleton of the story. Therefore an article describing a summer health camp receives very favorable publicity, due to the fact that most reporters can build up a good news story about almost any small incident from such a source. But given a similar amount of data on an orthopedic clinic, and the best attempts this reporter can produce are something like this sentence from an actual clipping: "One

hundred children were examined at these consultations, and 222 defects were found." The statistics were probably accurate, but as that was all the information that the reporter had at hand, he was unable to make a good news item. The fault lies with the doctor or health official who supplied such bare facts.

Too many reports of child welfare work, tuberculosis clinics, and free mental clinics, are written up merely as statistical statements, which cannot attract the attention nor compete for publicity with such sensational stories as a death from drinking liquor or the menace of a dead dog.

One would gain from the daily press the impression concerning free clinics that they are closed affairs in which the doctors and certain patients participated, despite the use of the word "free."

What interests a man concerning orthopedic clinics is where he may send his clubfooted office boy for advice. A worried mother wants to know to whom to go first with her problem—a mentally defective child. A medical student reads to learn the source and mode of transmission of the infection in a typhoid epidemic. All such items are the human interest points so often lacking in news articles which should have been supplied by the health officer, the health worker, and the doctor. Reporters cannot be expected to supply such information, but the doctor who knows the details should furnish them in order that these articles may afford the same news value as those about summer camps.

The daily newspaper should develop into a mighty health factor, if doctors supply reporters with detailed information concerning health matters, paying particular attention to points of human interest and educational value.

D E OVERTON, B.S

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this columns will be made for review, as dictated by their merits, or in the interest of our readers.

**ANAPHYLAXIS AND SENSITISATION** With Special Reference to the Skin and Its Diseases By R. CRANSTON Low, M.D., F.R.C.P. Lecturer, Diseases of the Skin, Edinburgh University 16 colored plates, 7 half-tone illustrations William Wood and Co, New York, 1925 Price, \$6.50

**THE INTERNATIONAL MEDICAL ANNUAL** A Year Book of Treatment and Practitioner's Index Forty-third year, 1925 William Wood and Co, New York Price, \$6.00

**AIDS TO PHYSIOLOGY** By JOHN TAIT, M.D., D.Sc., late Lecturer in Experimental Physiology, Edinburgh University, and R. A. KRAUSE, M.D., D.Sc. Second Edition William Wood and Co, New York, 1924 Price, \$1.50

**AN INTRODUCTION TO THE MIND IN HEALTH AND DISEASE.** For Students and General Practitioners Interested in Mental Work By WADDELOW SMITH F.R.C.S. (Eng.), Deputy Medical Superintendent of the City Mental Hospital, Nottingham William Wood and Co, New York, 1925 Price, \$4.00

**AIDS TO OBSTETRICS** By SAMUEL NALL, B.A., M.B., Cantab, M.R.C.P., Lond Revised by C. J. NEPEAN LONGRIDGE, M.D., Vict., F.R.C.S., Eng, M.R.C.P., London. Ninth Edition William Wood and Co, New York, 1925 Price, \$1.25

**A COMPANION TO MANUALS OF PRACTICAL ANATOMY** By E. B. JAMIESON, M.D., Senior Demonstrator and Lecturer on Anatomy, University of Edinburgh Second Edition William Wood and Co, New York. Price, \$5.00

**LUMBAR PUNCTURE, ITS ANATOMICAL AND PHYSIOLOGICAL RELATIONS** With an Appendix on Encephalography and Puncture of the Cisterna. By MARTIN PAPPENHEIM, M.D., Professor University of Vienna. Translated by GEORGE CAFFEY William Wood and Co, New York. 1925 Price \$5.00

**QUACK, THE PORTRAIT OF AN EXPERIMENTALIST** By ROBERT ELSON Small, Maynard and Co, Boston \$2.00 net

**COLDS, CAUSE, TREATMENT AND PREVENTION** By RUSSELL L. CECIL, M.D., Assistant Professor Clinical Medicine Cornell University Medical College D Appleton and Co New York, 1925 Price, \$1.00

**THE LIFE OF SIR WILLIAM OSLER.** By HARVEY CUSHING Two Volumes Oxford University Press, American Branch, 1925 Price, \$12.50

**HOW TO LIVE.** By PROF IRVING FISHER Yale University, and DR. EUGENE LYMAN FISK in Collaboration with the Hygiene Reference Board of the Life Extension Institute 12mo Cloth Illustrated. 541 pages \$2.00 net. Funk & Wagnalls Co, New York

**OLD AND NEW VIEWPOINTS IN PSYCHOLOGY** Some Interpretations and Applications of Psychological Principles By KNIGHT DUNLAP Professor of Experimental Psychology, Johns Hopkins University Baltimore The C V Mosby Co St. Louis \$1.50 net.

**RATS AND HOW TO DESTROY THEM** By MARK HOVELL, F.R.C.S., with introduction by S. L. BENSUSAN William Wood & Co, New York. Price, \$5.00

**SYMPTOMS OF VISCERAL DISEASE.** A Study of the Vegetative Nervous System in Its Relationship to Clinical Medicine. By FRANCIS MARION POTTEVGER, A.M. M.D., LL.D., F.A.C.P. Third Edition. Eighty-six Illustrations, Ten Color Plates The C V Mosby Co, 1925 Price \$6.50

**SOME FUNDAMENTAL CONSIDERATIONS IN THE TREATMENT OF EMPYEMA THORACIS** By EVARTS A. GRAHAM, A.B., M.D. Professor Surgery, Washington University School Medicine. Illustrated C V Mosby Co, 1925 Price, \$2.50

**PERSONAL AND COMMUNITY HEALTH** By CLAIRE ELSMERE TURNER, Associate Professor Biology and Public Health, Mass Institute Technology Illustrated. The C V Mosby Co, St. Louis, 1925 Price, \$2.50

**METHODS IN SURGERY** Used in the Surgical Divisions of Barnes Hospital, St. Louis Children's Hospital and Washington University Dispensary By GLOVER H. COPER, M.D. The C V Mosby Co, St. Louis, 1925 Price, \$3.00

**THE NORMAL DIET** A Simple Statement of the Fundamental Principles of Diet for the Mutual Use of Physicians and Patients By W. D. SANSMAN M.S., M.D., Director Potter Metabolic Clinic, Santa Barbara Cottage Hospital. Illustrated The C V Mosby Co, St. Louis, Mo., 1925 Price, \$1.50

**THE FAITH, THE FALSY, AND THE FAILURE OF CHRISTIAN SCIENCE.** By WOODBRIDGE RILEY Ph.D., FREDERICK W. PEABODY, LL.B., CHARLES E. HUMISTON, M.D., Sc.D. Fleming H. Revell Co, New York, 1925

**SURGICAL TREATMENT OF PULMONARY AND PLEURAL TUBERCULOSIS** By J. GRAVENSEN, M.D., Copenhagen, with a Foreword by S. Vere Pearson, M.D., M.R.C.P. Eighty-seven Illustrations (three in color) William Wood and Co, New York, 1925 Price, \$3.50

**THE CHEMISTRY OF THE BLOOD IN CLINICAL MEDICINE.** By O. L. V. DE WESSELOW, M.B. (Oxon) F.R.C.P. (London) William Wood and Co, New York, 1925 Price, \$4.50

**CANCER, POST-GRADUATE LECTURES** Delivered under the auspices of the Fellowship of Medicine. Edited by Herbert J. Paterson. Preface by Sir John Bland-Sutton LL.D., F.R.C.S. Illustrated. William Wood and Co, New York, 1925 Price \$4.00

**DIABETES, ITS TREATMENT BY INSULIN AND DIET** A Handbook for the Patient By ORLANDO H. PETTY, A.M., M.D. F.A.C.P., and WILLIAM H. STOVER, A.M., M.D. F.A.C.P. Illustrations and Tables F. A. Davis Co, Phila., Pa., 1925 Price \$1.50 net

**DISEASES OF THE EAR, NOSE AND THROAT** By HAROLD HAYS, M.A., M.D., F.A.C.S. 495 Half-Tone and Line Engravings 55 Full Page Plates F. A. Davis Co, Publishers, Phila., 1925 Price, \$10.00 net

**OPERATING ROOM PROCEDURE FOR NURSES AND INTERNES** By HENRY C. FALK M.D. with foreword by Eugene H. Pool M.D. With 275 Illustrations G. P. Putnam's Sons New York, 1925 Price, \$2.50

# BOOK REVIEWS

**PRECIS DE CLINIQUE SÉMIOLOGIQUE** (Diagnosis, Prognosis et Traitements) GASTON LYON, Ancien Chef de Clinique Médicale de la Faculté Masson et Cie, Editeurs, 120 Boulevard Saint-Germain, Paris 1924

In this volume an attempt has been made to unify the consideration of symptomatology, general pathology, therapeutics and diagnostic, and therapeutic technic. This method of exposition, which aims to present a subject as viewed from many angles at once, is to be commended. The lack of illustrations and the inadequate index are unfortunate features of the book.

HENRY M FEINBLATT

**OPERATIVE SURGERY** By J SHELTON HORSLEY M.D., F.A.C.S., Attending Surgeon, St. Elizabeth's Hospital, Richmond, Va With 666 Original Illustrations Second Edition The C V Mosby Company St Louis, 1924 Price, \$12.50

From the multitude of books brought out in recent months that of "Operative Surgery," by John S Horsley, is probably most deserving of consideration. The work covers the field of surgery viewed from the standpoint of the preservation of the physiologic function of the part under consideration and also the interpretation of the biologic processes that follows each operation. The operations described (the volume is limited to descriptions of the technique) are those which are accepted as the most logical for the lesions being discussed and are lucid in presentation. Explanations given for the choice of operations are clear as well as a fair criticism of those rejected. Of the later additions to surgery may be noted those of Lymphaticostomy for diffuse peritonitis and the late obstruction of the bowel. The operation for the innervation of the paralyzed muscle, Pylorotomy of Finney, Lobectomy as outlined by Graham, and the Intestinal Resection as practiced by Kerr, which lessens the likelihood of infection following the resection of the cecum. Thyroid surgery is reviewed and the advances noted. Frequent references are made to the work and results obtained at the Mayo Clinics. The opening chapter on Drainage is well worth careful consideration.

E W S

**INFECTION IMMUNITY AND INFLAMMATION** A Study of the Phenomena of Hypersensitiveness and Tolerance, and Their Relationship to the Clinical Study, Prophylaxis and Treatment of Disease. By FRASER B GURD, B.A., M.D. C.M., F.A.C.S., Montreal The C V Mosby Company, St. Louis 1924 Price, \$5.00

This volume is unusual, and at the same time interesting in that it presents an immunological subject from a surgeon's viewpoint. The author attempts to explain some of the complex phases of inflammation and infection in terms and manner which might be comprehensible to the practicing physician and surgeon. Details of technique are therefore purposely avoided and only general principles and theories discussed.

One of the fundamental hypotheses advanced by the author is that "anaphylaxis constitutes the first stage in the immunological reaction" and may be part of the physiological response of the body in inflammation and infection. That such a broad conception of anaphylaxis will meet with considerable opposition in immunological circles is inevitable.

To the immunological students who seek detail, or an unbiased presentation of all sides of the subject, this volume can be of little value. To the practitioner who seeks a casual and not too critical, glimpse into the subject, it may be of more service.

M W

**A CONTRIBUTION TO THE STUDY OF PERNICIOUS ANEMIA AND APLASTIC ANEMIA** By ARTHUR SHEARD, M.D. A Thesis presented for the degree of Doctor of Medicine in the University of Leeds, December, 1923. William Wood and Co., New York, 1924 Price, \$2.50

The volume is divided into three sections. The first dealing with Pernicious Anemia, the second with Aplastic Anemia, and the third devoted principally to case reports and analyses of cases.

In the first section, after an historical resume, the details of a series of fifteen cases of pernicious anemia are described. A clear definition is given conforming to the original one of Addison. The onset was slow and insidious in most of the cases with weakness the chief complaint in the majority. Other leading symptoms were pallor with definite yellow tint (fourteen cases), some degree of pyrexia (ten cases), prematurely gray and silky hair (eleven cases), glossitis and stomatitis (100 per cent of cases at sometime in the course of the disease). Undue smoothness of the tongue in irregular patches, on dorsum, denoting atrophy of the papillae, was found in most of the patients. Dyspeptic symptoms were found to have occurred in fourteen of the fifteen patients, principally vomiting, nausea, flatulence, abdominal pain and diarrhoea. Fourteen of the fifteen cases gave a history of dental caries or dental sepsis and all showed complete achlorhydria with a low total acidity. In four cases a palpable enlargement of the spleen was present. Other frequent symptoms were shortness of breath, palpitation, nervous disturbances, cardiac murmurs and persistently low blood pressure. In every patient normoblasts were observed some time or another, and megablasts in all save two cases. During the period of a definite remission it was rare to find even a single normoblast. The color index average was 1.126, but may fall below unity at some time in the course of the disease. A normal fragility of the red cells was found, proving a valuable feature in the differential diagnosis from hemolytic jaundice. Leucopenia was present in all but one patient, and a relative lymphocytosis in every patient. A yellow blood serum was always found, opposed to the nearly colorless blood serum of all other anemias.

Other features of the disease are analyzed in an interesting manner, and the subject of Aplastic Anemia is treated in detail. It is believed that the majority of cases of aplastic anemia bear no relation whatever to pernicious anemia.

A careful bibliography is appended. The book is well written, the cases carefully studied, and forms a valuable contribution to the study of the diseases of the blood.

W E McCOLLOM

**INTERNATIONAL CLINICS** By Leading Members of the Medical Profession throughout the World Volume I Thirty-fifth Series 1925 J B Lippincott Company, Philadelphia, 1925

The first two articles in this volume are written by L F Barker one dealing with Staphylococcus Septicemia and the other with the treatment of the Psychoneuroses. A section on Diagnosis and Treatment follows some of the subjects discussed being Group Medicine, Some Relationships of the Visceral Nervous System, Psoriasis, Surgical Diseases of Meckel's Diverticulum, and Exophthalmic Goitre in Children. In the last article a report of a girl, age nine years, is given where the result of treatment with tincture of iodine was very good. Sections on Mental Disturbances and Surgery follow. At the end of the book there is a review of the Progress of Medicine for 1924. This is comprehensive, covering about seventy-five pages.

As usual with this publication, the volume is a very interesting one.

# NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL 25, No 21

NEW YORK, N Y

OCTOBER, 1925

## PREVENTION IN PEDIATRIC PRACTICE\*

BY J H M KNOX, JR.,  
BALTIMORE MD

THE presentation before this distinguished body of a theme which is becoming current, if not trite, has for its excuse that although the importance of prevention is recognized in the medical literature of the day, its practice still lags far behind our knowledge, and it occupies in the routine day of the physician too small a proportion of his time and thought

It is estimated that there are approximately 1,500,000 cases of enteritis among the 5,000,000 of our infant population each year, that 700,000 instances of communicable diseases occur in early childhood, that there are today 15,000,000 school children presenting one or more remediable defects, and that 2,000,000 persons are infected for the first time with venereal disease annually in America

These and similar startling figures make it worth while for the doctor to consider if it is not essential that more of his individual effort, a greater proportion of his time and energy, should be devoted to applying such knowledge as he has to preventive work

"To make the unfit fit, is good" say Rankin, "but to make the fit fitter is even better"

Is it not true that at present most of the diseases occupying the attention of the medical profession have reached an advanced stage, few are treated in the early, and fewer still, in their predisposing stages? Treatment in anticipation, if possible, or threatened diseases, is *prevention*

The ideals of medicine, as distinguished from its practice, have always included the prophylaxis of disease and premature death, and the principles of medical ethics advise the members of the profession to take an active part in disease prevention in the interest of public welfare

The enormous task of controlling preventable maladies cannot be left to a small group of health officers, however competent. These indeed may be useful in organizing such social and professional machinery as is necessary to reduce

morbidity and mortality rates, but it the task is to be done in a large way, it must claim an appreciable part of the daily activities of all practitioners and they must function not only as expert diagnosticians and therapists, but also as hygienists. In their intrenched positions in their communities as trusted citizens and confidential family advisers, possessed of expert sanitary knowledge, the rank and file of the profession should accept the corresponding responsibilities and play a leading part in prevention if a successful public health program is to result

In speaking on this theme, the pediatrician has much to which he can point with pride, for much of his work, as it has developed, has been devoted to prevention, to keeping well children well. This is particularly true in his direction of the health of infants. He has encouraged parents to bring their well babies to his office at regular intervals. Through this method of early examination and advice, the pediatrician has demonstrated that not only the large proportion of time given to preventive medicine has been beneficial to the patient, and to the community, but also that it yields him satisfactory financial returns. It is possible, at least, in pediatrics to obtain from grateful parents a comfortable income derived in considerable measure from the guarding of well children

These statements may be pardoned in one who considers the care of children throughout their whole development—from the prenatal period through adolescence—not only the most interesting field of medicine but one which should contribute as much as any to the present welfare and future betterment of the race

The interest of the pediatrician in the welfare of the child should begin with a desire to improve the material with which he has to work. It is his evident duty to make the best physically, of the children under his care, whatever their handicaps may be, but surely no group of medical men are in better position to speak from firsthand knowledge of the many almost unsurmountable difficulties met with in dealing with the un-

\*Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 12 1925

fortunate human products which result from the mating of the unfit. The selection of parents with reference to the probable vigor, mental and physical, of their offspring may never be a possible achievement among men, but surely a more general movement to discourage the notoriously unfit, those below a minimum standard of mental development, those afflicted with disease which may be passed on to innocent children, a movement to prevent such classes as these from propagating their kind should be undertaken by the community and led by the medical profession. It would save untold misery and crime and in a few years would result in an enormous conservation of public funds if the moron and the criminal insane could be segregated during their reproductive years. Any individual, belonging to these groups, who, during this period improved sufficiently, could be released, but the method would greatly diminish the now constantly growing numbers of afflicted children who are at present crowding our public institutions or permitted to live without adequate restraint.

We are told that in Aosta, a district in northern Italy, for years there were many Cretins. They lived freely among the general population and their number was rapidly increasing. By law, in 1890, these unfortunate grown-up children were segregated. In 1910, after 20 years, a census of the district showed that there were only 3 Cretins remaining well past middle life. This seems to be a practical demonstration of the advantage which might be expected from the application of negative eugenics in the effort to improve the quality of our stock. There is also real danger to the maintenance of our racial standards because of the deliberate limiting of the number of their children by the more intelligent classes of the community. Ninety per cent of all women marry before the age of 40 years, whereas only 45 per cent of college women marry up to this age. Both our Puritan and Cavalier stocks are rapidly dying out. Men of science are producing about half as many children as their fathers. Whatever may be the causes of this change, whether love of personal comfort and luxury, additional brain activity, or the preaching of neo-malthusian doctrines, they do affect the quality of the pediatrician's material. Part of his duty would seem to be therefore to reduce the dross and improve the output.

It may be questioned, if the physical condition of a child is determined by heredity whether we have any responsibility in the matter at all. The truth is, however, that the average child rarely reaches the potentialities of its inheritance, and its failures are often those of environment. A relatively poor inheritance and a good environment may be better than the reverse. Twins with the same heredity differ widely from each other if their training and environment are dif-

ferent. Even Darwin held that "men differ less in capacity than in zeal and will."

It is our duty to improve the physical condition of each child by improving its environment, and this is, of course, most effectively done during the period of immaturity. It seems just as unintelligent for a physician, at least for a pediatrician, to be indifferent to the quality of the children that come under his charge as it would be for a tailor to be scrupulously careful of the fit of his garment but neglectful of the quality of his cloth. The quality of our race can be improved by

- 1 Weeding out the unfit
- 2 Discouraging voluntary infertility among the fit
- 3 Early and favorable marriages
- 4 Providing children with proper environment, food and training

Having kept congenial company thus far with the practical eugenicist on the trail of prevention leading to physical betterment, the pediatrician now joins company with the wide-awake obstetrician. Together they agree that the care of the infant begins at least 9 months before its birth and must be applied in his early period through adequate attention to the mother. We are learning that the great salvage of infant life that has been one of the most significant triumphs of preventive medicine of recent years has concerned almost exclusively the later three-quarters of the first year. The early infant death rate, that occurring in the first month, and which is nearly one-half of that of the first 12 months has been but little diminished. Moreover, the number of conceptions which are prematurely interrupted are at least 50 per cent of those which continue to term.

Every pediatrician is called to treat not a few infants born alive, it is true, but with too little vitality to continue the struggle even under favorable conditions. Some of them are syphilitic, others are ignorantly said to be suffering from congenital debility for want of a better term. Another group is made up of infants subject to convulsions, paralyzed or spastic from birth trauma and cerebral hemorrhage.

It has been conclusively shown that when the expectant mother is carefully examined early in her pregnancy and kept under competent observation through the whole period, and when her labor is skillfully conducted, not only is the maternal mortality from complications of child bearing greatly reduced, but also the neonatal death rate of the infant.

Sixteen thousand mothers (16,000) and more than one hundred thousand (100,000) infants are sacrificed each year in America, many of them because of the lack of these self-evident precautions. In rural Maryland more than one-half of the expectant women come under medical treatment only when labor has commenced—too late.

for any prenatal care. The conduct of the labor therefore which ought to be deliberately planned for, becomes an emergency operation.

It has been shown that many of the abortions voluntarily produced in the early months of pregnancy would be avoided if the anxious women could be sympathetically advised. At the Hopkins' clinic, the mortality of children born alive, of untreated syphilitic mothers, is 52 per cent, and that of children born of luetic but properly treated mothers, is but 7 per cent. The laity does not appreciate these facts. The responsibility of making them generally known rests largely upon the medical profession.

We now enter a high road in which the pediatrician is more familiar, namely, the care and the diet of the infant.

For years it has been the custom of many parents to put their young infants under the care of an experienced physician who directs the diet and controls the daily *regime*. Not a little of the present knowledge of nutrition has emerged from the laboratory or from the bedside practice of the pediatrician. He has long recognized the value of the calory and of the relative significance of protein, fats, carbohydrates, salts, and water, and recently has realized the importance of the vitamins. He has controlled and lengthened the intervals between feedings and has specified the needed amount of sleep, exercise, clothing, sunlight and fresh air. With his faithful lieutenant, the mother, and the experienced nurse, he has so controlled the whole environment of the baby as to bring it into the runabout period with a maximum of health and vigor. More than this, a large company of less fortunate infants born with a poor start, and suffering from malnutrition, have been added to the number saved and enabled to look forward to as healthy an older childhood as those who had continued well from birth. It is because infant care, such as has been briefly outlined, is becoming more general that the infant mortality rate has fallen so remarkably in recent years.

Unfortunately, however, as the period of infancy ceases and the runabout period begins the average parent feels that the time of danger is over and fails to realize that the older child should continue under the same kind of skilled medical oversight, and yet this so-called post-infant or pre-school period is recognized by the pediatrician as perhaps the most important of the whole life span. This is the age of rapid growth and development, physical and mental, it is the age when at present, at least, two-thirds of infectious diseases appear—it is the period when the great majority of preventable physical defects begin, it is the time also for habit and character formation, in short, a series of years of tremendous import to the whole future of

the individual, and one which should be guarded carefully and directed at every step.

The diet, the intervals of rest and recreation, the adjustment of the child to its home conditions, the protection from infectious disease, obtained by giving it an active immunity against those diseases of which we have specific sera or vaccines or by prevention of exposure to others through isolation and care. The use of supervised play in the development of self-control and team work, the development of proper health and mental habit, all these, and similar protective measures fall within the purview of the pediatrician cognizant of the results of laboratory investigation, and of the new work of the psychologists.

That the pre-school children throughout the country are as yet deprived of this prophylactic care is but too well known, and today troops of children are entering the lowest grade of our schools, public and private, mal-nutritive, unhappy or handicapped by physical defects which impair their health, retard their progress and more or less hobble them in the race of life. Is it not possible that the so-called common diseases of childhood, which so many parents now feel that it is just as well to have their children have and get them over with, are not so negligible as is supposed, but may leave scars or injury in the vital organs which in consequence fail to stand the strain of middle life?

The pediatrician who realizes the situation is often embarrassed in advising the return for observation and advice of older well children however much he appreciates the need. It is here that general public opinion and the testimony of parents whose runabout children have been helped will be of advantage.

The pediatrician is also interested in the health of the child at school though he is firmly convinced that the large amount of attention to the health of children of school age would be rendered unnecessary of the pre-school period were lived under competent medical direction.

The daily gathering of large groups of children in close contact in school buildings is at once a danger and an opportunity—a danger because conditions are present for the rapid spread of infection unless adequate precautions are taken, and an opportunity because of the facility by which health group instruction can be carried out.

Whether or not the health of school children is a primary responsibility of the school commissioners or the health department, whether these children shall be called school children or children of school age, is still debatable, but in any case, all matters pertaining to the health of children in schools should be directed by a physician interested and skilled in this field of work. He should pass on the construction of

the building, the air space, ventilation, lighting, wash room and toilet facilities, the type of desks and seats, blackboards and lockers, the school lunches, and other arrangements that have to do with the hygiene of the school life. Competent medical authority should supervise the instruction in health given to all grades and advise as to school hours, rest periods, and the recreation of the children. In co-operation with the teacher, the nurse or physician should arrange for the daily inspection and occasional examination of the children and direct the precautions to be taken to prevent the spread of communicable disease, and with the family physician advise as to the care of the malnourished or otherwise physically handicapped child.

Until the public becomes more thoroughly aroused concerning the neglect of the runabout, it is doubly important that school children should be kept as free as possible from unnecessary disease, relieved of bodily encumbrances and made physically fit as early as may be in their scholastic careers. With all this the pediatrician is much concerned.

The same kind of medical oversight should be provided for boys and girls under sixteen years of age in industry. The exploitation of child life in the last century in factory work

is one of the dark blots in our civilization. Our own country deserves much reproach for the neglect of its working children. Mental development may be checked, growth stunted and disease contracted because of the unhealthful conditions under which many young children are allowed to labor. In securing improvement in these matters, in preventing a child too young or otherwise unfit from undertaking hard labor, in bettering the sanitary conditions of factory life, in obtaining for each adolescent sufficient hours for sleep and adequate food, in all that concerns the health of the child, the children's doctor should be vitally interested.

These remarks need not be extended to indicate the enormous field in preventive medicine open to the pediatrician or to the physician whose practice concerns children. It is no less a task than to secure for every child in the land its unalienable birthright, fit and healthy parents, and the opportunity to pass its years of growth and development in a suitable environment as free as possible from preventable defect and disease.

I believe that this field in prevention offers the pediatrician satisfactory financial returns, but even more than that, the satisfaction of having "done his bit" in bettering the succeeding generation.

## MENTAL HYGIENE OF THE CHILD AND ITS RELATION TO MEDICINE\*

BY D. A. THOM, M.D.,

BOSTON, MASS.

**P**EDIATRICS and child psychology are mutually dependent one upon the other. The pediatrician who fails to take into account the mental as well as the physical welfare of the child is no more efficient or less responsible than the psychiatrist who endeavors to interpret all the ills of mankind in terms of mental conflicts. The body and the mind rarely if ever operate independently one of the other. The cause of a bodily condition or mental ill health may be either predominately physical or psychological, that is, organic or functional, but rarely does it ever remain long so well defined.

Vomiting in a child often has its origin in imitation, worry, fear, but if it persists over a very long period of time physical manifestations will soon develop. The child may be subjected to an acute infection or an accident which ordinarily goes on to an uninterrupted recovery, but under certain undesirable home conditions an atmosphere of sickness is built up around the child incapacitating him for a normal healthy adjustment to life long beyond the usual convalescing period.

A little girl eight years of age was seen first by the family physician because she was under weight, tired easily, extremely irritable, and was considered by the family as an extremely difficult feeding problem. She was finicky about the types of food she would consider at all, and then would play about with her food sometimes for an hour and a half during meals, the problem of taking food always being more marked in the morning, the mother stating that she got so worked up and upset about the child's taking breakfast that five mornings a week, at least, the mother would lose her own breakfast. (This being an indication of the emotional instability of the mother.) The child was coaxed, teased, bribed, and punished with little or no effect. It took nothing more than a careful inquiry into the home situation to be fully convinced that the child was utilizing the meal hour as a time to attract attention, and was enjoying the fact that her undesirable habits of eating were keeping her in the limelight.

After explaining the child's motives to the mother, and getting the family's co-operation, improvement took place immediately. The exploitation of symptoms which well may have had some physical cause which long since have

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, May 12, 1925.

been removed, is not at all uncommon. The following case is a good example.

A child, six years old, went through a severe attack of whooping cough which lasted from May until September. During this period she had severe paroxysms of coughing which were occasionally followed by a moderate amount of rigidity in the extremities, and an apparent loss of consciousness. For several months after the child had been thoroughly examined at the Children's Hospital and a competent pediatrician had stated she was free from the original infection she would frequently have spells which the mother described as follows: the child would start coughing and fall to the ground, become stiff, her eyes would close and it seems that she knew nothing of what was going on about her. It was found, upon investigation, that these spells invariably occurred under emotional stress and strain, or when there was an impending punishment by one of the parents; in fact, they were utilized to get the child out of any difficult situation.

The mother was extremely worried and oversolicitous and whenever there seemed to be the slightest evidence that the child was about to have a spell the environmental situation was adjusted to her liking. This invariably aborted an attack. It seemed quite obvious that here again we were dealing with a psychological situation rather than a physical one, and enlightening the mother as to the motive of the attacks and assuring her there would be no danger in ignoring them, relieving her worry and anxiety and eliminating her over-solicitous attitude toward the child, this annoying and rather difficult situation was completely alleviated in two weeks.

In the foregoing cases the physical symptoms were sufficiently annoying and inconveniencing to the parents to make them seek medical assistance, but unfortunately all too frequently the problems of the child are of such a nature that they do not present themselves in a very spectacular way, in fact they tend to minimize the necessity of parental supervision.

Shyness, jealousy, fears, day dreaming, feelings of inferiority or perhaps the mental conflicts find expression in tempers, destructiveness, cruelty, lying, stealing or truancy, and here again it is often met as a disciplinary problem and measures are instituted to squelch the rebellion. Threats, attempts to frighten or beat the child in submission does nothing more than exaggerate and perpetuate the mental conflict.

The rod is about as useful in trying to cure diphtheria as it is in altering the conduct which is activated by motives unconscious to the child.

The general practitioner or pediatrician who neglects to take into consideration the mental side of the child's life is failing to utilize a very important instrument not only in dealing with un-

desirable habits such as enuresis, feeding problems, poor sleeping habits, night terrors, persistent fears, personality deviations, such as shyness, jealousy, pugnacity, delinquent trends as lying, stealing, truancy, but also the frequent personality changes and conduct problems that follow physical disease and accidents.

E. J. was a lad, seven years of age, who was sent to the Out Patient Clinic of the Psychopathic Hospital because of a marked personality change which followed a head injury. The patient had been in the hospital for a period of three weeks, seriously ill with a question at that time of a fractured skull. However X-rays and neurological examinations failed to reveal any evidence of an organic brain lesion. The patient was sent home, in bed for four weeks, during which period he became very irritable, extremely selfish, sullen, resentful, and when he got up and out with the other boys began to have fits of temper and soon became either ignored by the group or picked upon by them. He was nicknamed "empty head."

Legal proceedings were about to begin when the mother brought the patient to the clinic. One found that after the illness the entire family's attitude changed and the household began to revolve around the patient, everything was his to accept or reject. For the first time he found himself in the limelight. The other children, of which there were six in the home, were all impressed by the fact that their brother had been seriously ill and that he must be catered to and he soon found that his selfish, domineering ways began to get him things in the household especially that the other children were denied.

Although we could not be positive in this particular case that the personality change was due to the altered environmental situation, it seemed more than likely that it was the case, and the treatment was instituted along these lines, that is, instructing the parents as to the best way of managing this altered personality. In less than a month the child was his old happy, cheerful, unselfish self, competing and co-operating with the gang in a perfectly normal manner.

Mental hygiene is that branch of preventative medicine which has to do with the preservation of mental health. We are very apt to dodge the issue of poor mental health unless the patient is already deluded, hallucinated or intellectually deteriorated, this fact is brought out by the long duration of the symptoms of mental illness before the average individual will seek medical assistance, and the long time intervenes between seeking assistance and following the advice given. Mental illness, like physical illness, exists in all degrees from the earliest symptoms of poor adaptation to the problems of every-day life to final and complete mental delapidation of a frank psychosis. Some of the less severe forms of

mental illness (commonly called psychoneurosis or just nerves) are frequently more incapacitating than the definite psychoses. But the prognosis is far more encouraging, in fact, if recognized early and treated intelligently a large per cent make complete recoveries. There seems to be a direct relationship between the duration of the symptoms and the success of the therapy. And in a general way much more can be accomplished in the younger patients than in the older ones. It therefore seems but reasonable to expect better results in dealing with children whose dormant mental characteristics are still very plastic, whose reactions to their environment are not colored by experience and education.

If mental hygiene is to be of real service to the world at large it must be practiced in the home, school, on playgrounds, in gymnasiums and in our general relationships one with another.

I would take this opportunity of stressing the importance of painstaking and detailed history in every case where there is a conduct problem and in those cases which do not respond to the usual therapeutic measures which are applied on the physiological level. The general practitioner and pediatrician will frequently find the answer to many a baffling symptom or syndrome in some obvious environmental situation. It may be the child is caught between clashing personalities in his own home, he may be finding a refuge in illness from his failure in school or on the playground. Perhaps his mother is the type who refuses to allow him to grow up or his father is a stern, rigid, forbidding disciplinarian, who is starving the youngster's emotional life. Not infrequently we find some physical illness has placed the child in such a desirable position in the family group, made him in the center of the

stage, so to speak, that the child will cling tenaciously to the symptoms long after the physical cause has been removed. (It is not unusual to find the soldier developing a *neurosis* while he was recovering from a wound.) The attitude of the parents and physician toward the illness or incapacity of the child is tremendously important. We must remember suggestibility and imitation are two of the most dormant characteristics in the child life so that one must not develop an atmosphere which suggests illness or create motives for the exploitation of symptoms.

The point I started to emphasize was that if the physician would investigate the family history and general environmental situations with more care he would find very frequently the underlying cause or causes of many of the undesirable habits, personality deviations and moral twists seen in children. In many instances the necessary therapeutic measures would thus be perfectly obvious.

There are, however, a sufficiently large number of cases which need more than a painstaking history, a careful analysis of the whole family problems must be undertaken, it's a long, time-consuming task which will tax the skill and patience of those best fitted by training and experience to do the job. Here is where the psychiatrist and psychologist and social worker render valuable assistance.

The mental health of the child just as the physical health is in a very large degree in the hands of the general practitioner, and not the specialist, and in assuming the responsibility he should utilize as one of his important instruments the knowledge which has gradually been collected under the subject of mental hygiene.

## MENTAL HYGIENE OF THE CHILD AND ITS RELATION TO THE DEVELOPMENT OF CHARACTER\*

BY IRA S. WILE, M.D.,  
NEW YORK CITY

**C**HARACTER is the combination of qualities distinguishing a person. In a more specific sense it is applied to a man's strongly marked traits, especially those distinctive qualities dependent upon conscious choice.

Mental hygiene may be partly interpreted as those principles of human guidance which favor normal mental functioning. It involves a composite application of psycho-prophylaxis and psycho-therapeutics. It is not to be regarded as related only to mental defectives, epileptics, neurotics and the psychotic. It is obvious that, under the broad definition, men-

tal hygiene possesses definite values in relation to the development of character which, expressed in conduct, evidences mental function. Its purpose is constructive, protective guidance into normal social living, which alone is conducive to the highest character.

Every physical phenomenon has a psychic effect, and every psychic factor involves some physical response. Children respond to internal reactions of their physical organization, and are likewise influenced by persons, objects, and circumstances. The combination of their physical and psychic reactions enters into and fosters the development of their traits and helps determine their respective qualities and

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 12, 1925.

quantity for making adaptations. Character may be regarded as the integrated responses of an individual as manifest in behavior.

The basis of character development lies in the establishment of habits and mental hygiene is concerned with habit formation. A knowledge of habitual reactions, in a sense, serves as the basis for the predictability of conduct under varying circumstances. Mental hygiene is involved in securing responsiveness or inhibitions, both of which may be regarded as measures of character.

Mental growth of children is conditioned by their anatomical and physiological variations. Unfortunately the direct relations between physiological processes and mental function are not known. It is necessary, however, to view character development in terms of mental function as related to the various factors conditioning it.

Inasmuch as character is a generic term, it is possible to refer to various sides of character as though they were units. It is unsound, however, to accept any specific quality or trait as though it were representative of character as a whole, even though for a time, it may appear to dominate mental activity. Character possesses components arising from every element of structure and function. Hence, mental hygiene must take cognizance of those elements of well being which ordinarily would be deemed purely physical. It is apparent that congenital endocrine disturbances, such as cretinism, are significant in altering the mental functions of a child, and thus interfere with the potentials of character development. A club foot, equally congenital, may indirectly handicap intellectual function, but its limitations upon activity indicate its possibilities for handicapping normal mental growth. Mental hygiene, therefore, is as much concerned with the correction of special deformity as it is in the supplying of a needed endocrine substance in order to provide a fuller opportunity for normal self-expression. Ophthalmia neonatorum, or any other form of blindness, calls for personal adjustment physically and mentally, and, therefore, is within the field of mental hygiene. Various disease sequelae, such as deafness and arthritis, hamper physical activity, limit intellectual effort, and may interfere severely with moral judgment and rational social behavior. Enuresis, whether functional or organic, calls for habit training, physiologic readjustment and adaptations to life that concern those responsible for the training of children. Constipation, regardless of its causation, produces effects which militate against health, and more particularly so, because of the current fetishes with reference to the importance of evacuations. The establishment of correct habits for the excretory functions are

mentally hygienic as well as physically hygienic. The student of childhood is constantly impressed by the effects of malnutrition and fatigue upon the mental attitudes and capacity for intellectual effort, as well as by their influences upon daily behavior. Many instances of pseudo mental deficiency, irritability, stubbornness, tantrums, moroseness and insolence are merely manifestations of under-nutrition, lack of sleep, or over work. Numerous infections of chronic type, as sleeping sickness, impair normal living and seriously affect character. It is thus apparent that mental hygiene requires a direct attack upon the physical elements of well being in so far as they constitute factors in mental function. A marked strabismus may be a greater factor in determining character traits than mental dullness. Any physical handicap, which produces limitation in physical function, is accompanied by psychic effects that may influence character disadvantageously. The physical basis of mental hygiene is of tremendous importance.

Intellectual power is significant but it is not necessarily dominant for the development of the finest traits of character. During the earlier days of intelligence tests, the discovery of feeble-mindedness was deemed a sufficient explanation for almost any type of misconduct. This viewpoint is hardly tenable. In order to guide childhood it is necessary to learn the intellectual potentials of a child so as to create a rational program for its guidance. This holds equally true for the supernormal children as well as for those who are mentally subnormal. It is necessary to ascertain the special abilities or disabilities of children regardless of their intelligence levels, in order to promote their mental welfare. Temperament may carry some implication concerning the quality of intelligence but it does not indicate the level of intelligence. There is a vast distinction between the ability to form moral judgments and moral behavior. Intellectual levels cannot be regarded as measures of character though they are important in suggesting methods essential and useful for the guidance of character.

The mental defectives, particularly the moron and the borderline types, present special problems to the mental hygienist, but, relatively, the character difficulties they present, are no more numerous than those found among children of the highest intellectual capacity. The inculcation of habits of right living, in the broader sense, calls for early acquaintanceship with mental capacity, as differentiated from mental traits. Frequently inherent traits and attitudes may account for failure in intellectual achievement. More commonly intellectual limitations help to account for the exhibition of mental traits, irrespective of the intellectual levels. The mental hygienist seeks to secure the proper adjustment of mental

effort and mental capacity, so as to provide for the maximum of satisfying achievement. To secure an adjustment of this type, it is insufficient to depend merely upon the determination of intelligence levels. The routine determination of mental age of children is valuable but insufficient, from the standpoint of mental hygiene, to make provision for the adjustments required for the evolution of desirable traits of character. The child with an intelligent quotient of one hundred and sixty or above may present the same character traits as those exhibited by a child with an intelligence quotient of sixty or seventy. In both instances similar basic thwartings and limitations may be responsible for the undesirable manifestations of behavior. The underlying desires for success, power, independence, and dominance, may be activating each of them, but the methods for satisfying these desires vary greatly because of their respective intellectual potentials. It is necessary, therefore, for the mental hygienist to recognize the values of intelligence tests in terms of the definite information they supply. They are not to be regarded, however, as the explanation of conduct, whether favorable or unfavorable. Obviously the intellectual components of character are important, but for the most part, they are not diagnostic nor completely explanatory of character. They reveal certain qualities of mental function but they do not yield information concerning some of the most vital characteristics requisite for social life. They cast little light upon initiative, leadership, inventiveness, kindness, sympathy, courtesy, obedience, or rectitude. They give insight into powers of memory, association, comprehension, reasoning and judgment, all of which are factors in securing adaptations to social life. To a great extent it is out of these adaptations that character emerges. Complete intellectual adjustment in itself does not guarantee moral behavior. It is essential, nevertheless, for the mental hygienist to recognize the value of intellectual adjustments as a factor in child guidance.

The interplay of physical and intellectual factors is recognized but they are especially bound up with the emotional life of children. An appreciation of the emotional contents of children's minds is essential because they are the most vital motivating forces in activity. Character growth is dependent upon the guidance of the emotions. Habitual emotional reactions tend to become fixed and crystallized into attitudes and sentiments which constantly affect personal adjustment. The tyrannic selfishness exhibited in anorexia nervosa merits early attention so as to forestall later neurosis or hysteria. The hygienist seeks to overcome the thwartings of desire and to present opportunities for the reasonable expression of emotional life through opportunities for self-satisfaction. The pleasure and pain

must be weighed in terms of the balance of self-assertion and self-submission. It is imperative to recognize the emotional elements bound up in the self-preserving ego instinct, the emotional qualities surrounding the herd instinct, and the forceful strivings attached to the sex instinct. It is equally important to appreciate the planes of conduct which are normal at various ages of individual development. The child is for many years bound up in himself, and his judgments and activities are unrelated to the welfare of others. A considerable degree of training is required to bring about the emotional controls, essential for deriving pleasure from experiences involving the welfare of human beings other than himself. The interpretation of rage, temper, pugnacity, shyness, lying, stealing, demands an analysis of the emotional content entering into such behavior.

Emotions are states of tension having their origins in conscious and subconscious living, they constitute the dynamics of character. It is obvious that the conscious life of the child is not the sole determiner of character. The subconscious motivation also is important in moulding it. The mental hygienist is obliged to analyze the emotions and emotional conflicts in order to suggest the sublimation of numerous impulses which arise in part from the physical status of the child, his intellectual potentials and his conflicts with the world in which he lives. Shame, slowness, stubbornness, defiance, peevishness, stolidity, indolence, may arise from the thwarting of self-assertive trends, whose needs must be determined.

The mental conflicts arising from the clashing of desires must be ascertained and eliminated. Character attributes have their basis in the instinctive and emotional life, and cannot be modified without an investigation and appreciation of them. Continued conflicts even before repression, profoundly affect mental function.

The early recognition of neurotic and hysterical trends is the basis for stabilizing emotional activity which is so essential for an equilibrium of mental function.

The social phases of character indicate the value of an understanding of the social forces acting upon child life. The child in isolation is a useless being and his qualities are of little concern. The child in relation to his environment evidences attitudes which are largely determined by the interaction of the social forces upon his innate potentials. Were the mental hygienist to focus all his attention upon the child, his service would be limited. Only by seeking out the social influences affecting child success and happiness can he be an intelligent guide and counsellor. One need but suggest the effects of poverty, alcoholism, ignorance, parental indifference, neglect and misunderstanding, desertion and divorce,

secular schooling and religious education, to appreciate the multitude of forces that enter into the child's world. To attempt to guide character development without endeavoring to create a favorable environment for the growth of desirable habits and attitudes is irrational.

Character does not arise wholly from innate internal patterns. The impingement of the world upon the child helps to determine the attitude of the child towards the world. The mental hygienist is deeply concerned with environment, with familial background, home conditions, methods of schooling, companionships, recreational opportunities, vocational aptitudes and interests, and with the personalities most constantly and frequently in contact with the child. Successful living is dependent upon free adaptation to life and the ability to make adjustments essential for health, comfort, and happiness. One does not disregard the exhibition of character traits similar to those found in other members of the same family, but there cannot be an assumption that these traits are inherited and unchangeable. Such a fatalistic point of view precludes an intelligent approach to the problems of character formation. If one assumes incorrigibility, mental hygiene would be useless.

The mental hygienist directs his attention towards the main requisite for bringing about normal mental function as the basis of rational character development. With an appreciation of the physiological and psychological constitution of the child, with an insight into his emotional relationships, he seeks to develop a definite plan for life guidance, with the child as the center of

activity. Around the individual child, however, are groups of elements radiating toward him. The child is viewed as an individual, but more completely in relation to his world of institutions, laws, and opportunities. Definite programs for adaptation and readjustment are developed. By nature children are imitative and suggestible, egocentric but reasoning, and hence, guidance in development becomes possible. The early recognition of desirable and undesirable character trends supplies a real opportunity for intelligent assistance in the art of living.

The mental hygienist is not merely a character analyst, his main function is synthesis, based upon his analysis. His aim is to promote a sense of security, a feeling of self-satisfaction and a consciousness of expansion for more complete living. He attempts, through an adjustment of the environment, to bring about a conscious willingness to accept personal limitations and to make adaptations in consonance with the realities of life. Conscious choice is not to be disregarded even though a high degree of motivation arises from subconscious interests and strivings. The soundest character development is dependent upon the conscious choice of traits that are personally satisfying. Character evolved from conscious selection of traits is established upon firmer foundations than that arising from coercion, over-direction and compulsive over-solicitude. Mental hygiene finds its greatest service in interpreting the world to the child and the child to its world, thus liberating and guiding the dynamic forces bound up in the development of character.

## THE SURGICAL ASPECT OF THE NASAL GANGLION\*

By SIMON L. RUSKIN, M.D.,

NEW YORK CITY

THE surgical aspect of the nasal ganglion has hitherto received but little attention in comparison with its importance. Although cocaineization of the ganglion intranasally by superficial application has been employed especially for the submucous resection of the septum, nevertheless, for radical sinus work the anesthesia of the ganglion by direct injection has seldom been used. This seems strange when one considers that the ganglion is one of the main centres for innervation of the nose and throat and can be blocked with one-half of a cubic centimeter of 2 per cent novocaine. The reason for this apparent neglect of such a useful measure lies in the fact that the nasal method of approach to the ganglion quite often presents technical difficulties that make the injection more bothersome than the diffuse cocaineization of the nasal mucous membrane.

In the February issue of the *Laryngoscope* I have described the injection of the nasal ganglion through the posterior palatine canal. Through this route one can inject the nasal ganglion almost with the same ease as an ordinary subcutaneous injection. This route is independent of any intranasal condition, has a direct and easy approach through the mouth, is in constant relationship to the ganglion and has practically no danger of hemorrhage. In addition, the same route brings the needle in close relationship to the maxillary division of the trigeminal nerve so that the injection of the ganglion and the maxillary nerve can be done simultaneously, thus securing a very extensive region of anesthesia in a quick, easy manner. I have recently had the pleasure of demonstrating to Dr. Greenfield Sluder this

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 13, 1925.

method of injection on the cadaver, and of showing him several unusual types of cases where the ganglion was successfully injected through this new route

On reading the article written by Silverman, the dental surgeon, in the A. M. A. describing the injection of the maxillary nerve, through the posterior palatine canal it occurred to me that I could reach the nasal ganglion through the same route. In attempting the injection, on anatomical material, I found that the ganglion could easily be reached in this way, and on clinical trial was gratified to see the thoroughness of the effect.

To fully realize the value of this injection, one must consider the extensive distribution of the nasal ganglion. The ganglion has four main groups of branches, an internal or nasal group, a descending or palatine group, a posterior group and an anterior or orbital group. The internal or nasal group sends a number of branches, the largest of which is the nasopalatine nerve through the sphenopalatine foramen to pass medially across the lower part of the anterior wall of the sphenoid to the septum, thus supplying the major portion of the septum. From the same group also arise branches to the middle and superior turbinates, superior meatus, sphenoid sinus and posterior ethmoidal cells. The nasopalatine nerve, passing as it does, obliquely across the septum in a groove in the vomer and septal cartilage and through the anterior palatine foramen where the nerves of each side meet and form a small plexus, reaches the roof of the mouth, and supplies, in addition to the septum, the anterior portion of the hard palate and incisor teeth.

The descending or palatine group of branches from the sphenopalatine ganglion comprise three large nerves, the anterior, middle and posterior palatine. These three branches associated with the posterior inferior nasal nerve descend almost vertically from the sphenomaxillary fossa into the pterygopalatine or posterior palatine canal. The posterior inferior nasal nerve leaves the canal through a small perforation to be distributed to the posterior two-thirds of the inferior turbinate and inferior and middle meatus. The nerve runs along the superior margin of the turbinate. The anterior palatine, which is the largest branch, emerges at the posterior palatine foramen to be distributed anteriorly over the roof of the mouth and medial side of the gums. The middle palatine nerve leaves the pterygopalatine canal to enter a small accessory palatine canal and emerge on the small pyramidal process of the palate bone to be distributed to the soft palate, uvula, upper two-thirds of the faucial tonsil and pillars. The posterior palatine nerve also leaves through a small accessory palatine canal and is distributed to the

same area. In addition to sensory fibres, this nerve also contains motor fibres supplying the levator palati muscle.

The posterior group also sends several branches to the extreme superior part of the nasal cavity, nasal septum, sphenoid sinus and a pharyngeal branch to the nasopharynx, superior part of pharyngeal wall and medial part of Eustachian tube.

The anterior or orbital group consists of a number of small branches which leave the ganglion passing upward and anteriorly through the inferior orbital fissure supplying sensation to the periosteum lining the orbit, and some branches passing into the posterior ethmoidal cells.

Arnold and Longet describe some branches passing upwards to be distributed to the neurilemma of the optic nerve. Bock and Valentine have observed a branch from the ganglion to the sixth nerve. Tiedman found a branch from the sphenopalatine to the ciliary ganglion. Luschka describes two or three branches, sphenothmoidal ascending to the superior portion of the internal orbital wall, passing through the posterior ethmoidal foramen and entering the brain case.

The nasal ganglion together with the maxillary nerve, both of which can be anesthetized at the same time, supply the integument of the cheek, forehead of the temple, the lower eyelid, the side of the nose and upper lips, most of the lining membrane of the nose, and the mucus membrane of the upper part of the pharynx, of the antrum, and posterior ethmoid cells, the soft palate, upper two-thirds of the tonsil, the uvula, and the glandular and mucus structure of the roof of the mouth. The mere recital of this distribution is enough indication of the value of this route of injection.

This injection has proven of value in tonsillectomy where an injection of half a c.c. of novocaine into each ganglion supplemented by 1 c.c. of novocaine at the base of each tonsil for the glossopharyngeal plexus has given total anesthesia. Although block anesthesia of the middle and posterior palatine nerves at their emergence from the accessory palatine canal has been practiced, nevertheless, I have been unable to find references to the injection of the ganglion directly for tonsillectomy.

In radical antrum operations the injection of the ganglion and maxillary nerve, by the new route has given a complete anesthesia.

For radical ethmoid and sphenoid surgery the ganglion has given extensive anesthesia. One must, of course, remember that the anterior and posterior ethmoidal nerves are not affected by the ganglion injection.

For the submucous resection of the septum the usual block anesthesia is sufficient, but in cases where the deflection is very great, mak-

ing the posterior part inaccessible, the ganglion injection by the posterior palatine canal is very useful

The injection also has a wide range of usefulness in oral surgery for the removal of neoplasms of the upper jaw and mouth

The technique of the injection is very simple after the regional anatomy has been mastered. The sphenopalatine ganglion is usually described as situated in the sphenomaxillary fossa midway between the anterior border of the sphenoid bone and the posterior border of the maxillary bone and 5 to 6 mm beneath the second division of the fifth nerve as it bridges the pterygopalatine fossa. In dissections I have found the ganglion to lie rather close to the sphenoid, separated from the periosteum by a thin layer of fascia. The ganglion is hung a few millimeters below the maxillary nerve and appears to be slung between the maxillary nerve laterally and the Vidian nerve medially. Anterior to the ganglion is the fairly large sphenopalatine artery and a sheath of fascia surrounding it. The fascia surrounding the ganglion is quite distinct and can be seen extending down into the posterior palatine canal to about the level of the inferior turbinate. Laterally the fascia encircles the

maxillary nerve, forming a sort of diaphragm. Thus fluid injected into the ganglion region can diffuse up to the retro orbital structures, causing a temporary amblyopia or transient abducent paralysis. The ganglion lies in close proximity to the sphenopalatine foramen. Above, the ganglion is covered by the under surface of the sphenoid and orbital process of the palate bone, behind by the pterygoid process and greater wings of the sphenoid, anteriorly by the maxillary sinus, and laterally, and inferiorly by the sphenomaxillary fossa.

Injection of the ganglion was formerly done by one of two routes, either through the nose, as suggested by Sluder, or through the mouth, passing the needle lateral to the last molar tooth and behind the tuberosity of the maxilla into the sphenomaxillary fossa. This latter route is the one generally used by the dental surgeons. The posterior palatine route which I suggest for the nasal ganglion differs from the above routes in that the needle is guided through the posterior palatine foramen into the posterior palatine canal at the top of which sits the nasal ganglion. The nasal ganglion sends the palatine nerves almost vertically down into the posterior palatine canal. By sending the needle upwards in the same direction one is guided like in a grooved

director exactly to the ganglion.

To enter the canal one first locates the posterior palatine foramen. This opening is usually round, quite large and as seen in the illustration lies opposite the second or third molar tooth. One palpates the edge of the hard palate posteriorly and inserts the needle one-half a centimeter anteriorly and about three-quarters of a centimeter medial to the teeth. In edentulous mouths one is of course guided more by palpation of the hard palate. In these cases, however, the posterior palatine foramen is larger than usual, thus making it relatively easy. The posterior palatine foramen varies in its position, sometimes opposite the third molar tooth, at other times opposite the second, or it may be oval in shape and quite close to the alveolar process. One is therefore obliged occasionally to probe with the needle to locate the opening. Another guide to the foramen is an occasional dimple in the mucus membrane of the palate in this region. This dimple is sometimes paler or redder than the surrounding area.

Needle in Posterior Palatine Canal for  
Injection of Sphenopalatine Ganglion

For the injection of the ganglion I employ a 22 gauge platinum or flexible steel needle, 4.5 cms long, mounted on a syringe at about a 45 degree angle. With the patient in the lying position and head extended, the posterior palatine canal which is almost vertical in the sitting position is brought almost horizontal. In this position I have found injection easiest, although it can be done in the sitting position. After the posterior palatine foramen is located the needle is inserted through it into the posterior palatine canal for a distance of 3.0 to 4 cms. This brings the needle point into the ganglion and opposite the sphenopalatine foramen. For the injection of the maxillary nerve simultaneously with the ganglion the needle is carried in 4.5 cms. There are several points to be remembered in this injection. The needle point must be directed in a line towards the inner canthus of the eye rather than towards the pharynx as one is strongly tempted to do. The mouth must be opened as wide as possible to permit the entrance of the needle in the proper direction. With some patients it is advisable to use a

avoided to prevent its breaking. It is also advisable never to bury the needle to the hilt, to avoid difficulty in extracting the fragment should the needle break. This accident is not more frequent in this injection than in injections elsewhere.

The injection should be done with strict asepsis. The roof of the mouth is painted with half strength iodine and the tongue kept depressed to avoid contaminating the area or the needle. For anaesthesia 2 per cent novocaine is preferred, 1 cc usually sufficing. For neuralgia injections either 10 minims 70 per cent alcohol or 5 per cent phenol in alcohol is used.

Up to the present time I have seen no untoward complications. There has been no case of severe hemorrhage following the injection. Should a vessel be punctured the pressure of the surrounding tissue would probably produce hemostasis. There is, however, a little bleeding from the palate for a few moments following the extraction of the needle. Occasionally one may observe a transient amblyopia or abducent paralysis, but this wears off in

mouth gag. The tongue should be kept depressed to avoid its contaminating the needle. If the canal has been entered the needle will slide in for almost its full length, otherwise it will enter the palate for only one to two cms. If one goes behind the posterior edge of the hard palate the needle slides in easily, but instead of being in the canal it has merely perforated through the soft palate and the fluid runs into the pharynx, or appears mixed with blood in the nose. If the needle was placed through the soft palate more laterally it will slide along under the mucus membrane of the lateral wall of the nose and the fluid will be deposited in the vicinity of the sphenopalatine foramen. In such event, anaesthesia of the ganglion would occur by infiltration. At all times leverage on the needle must be

a few hours. One case complained of some burning sensation and pain on movement of the eyeball for several weeks following the alcohol injection. In some cases I observed a swelling of the cheek on the side injected, associated with a moderate amount of tenderness.

In conclusion, I wish to point out again that injection of the nasal ganglion is a valuable aid in securing anaesthesia for nose and throat work, and that the ganglion can be easily approached through the posterior palatine canal. In addition this route of injection has a wide range of usefulness in cases of nasal ganglion neuralgias.

The accompanying cuts show the syringe used for the injection and also a fine nasal ganglion applicator for local applications in the nose.

## THE NEWSPAPER AS AN AID IN PUBLIC HEALTH WORK \*

By LEO F SCHIFF, M.D

PLATTSBURG N Y

**P**UBLIC health, being the health of the public, is therefore, a matter of utmost concern to the public themselves, and not merely a series of official acts. There is no better way of keeping the public acquainted with the health conditions in their community and to enlist their support than through the public news agency—the newspaper. My topic of today concerns itself particularly with the local (community) aspect of public health publicity work, and more particularly to that of the smaller communities. The State Department of Health and many other public health and charitable organizations, have been using the newspapers, moving pictures, and other means of publicity for several years in furthering great health movements and in educating the public in a general way. I am speaking particularly of the way in which the public health agencies of a small community may interest their local public in their own welfare from day to day and with reference to the varying conditions as they arise.

The newspaper's business is to print the news. The staff of the papers are constantly on the lookout for news, and they are glad to receive and print whatever comes to them as news. They receive a great deal of material sent out by the large health agencies and societies of various sorts, including some which is propagated to further movements which are not always of real benefit to the public, but rather propaganda of a non-representative group of fanatics or in some cases of various cults and sects. The editor and reporter are busy men and cannot take time to sift the wheat from the chaff. Whatever looks, at first glance, to be news is grist for their mill, and goes to the press room. A great many newspapers are buying syndicated health items, which tell us what to eat, what to wear, how to breathe, how to exercise and so on. None of the material described above gives the public the kind of information to which I am particularly referring in this paper, that is, what is going on in regard to the public health of their own community at the present day.

Quoting from my own experience, the easiest way to handle this situation is for the Health Officer to conduct his own column for which the daily papers are usually glad to grant him all the space he wants, and to supply the material for this column himself from the items of his daily routine and such other matters as

may come to him from time to time. It is far better to control the work in this way than to give it to the reporter or editor in abstract for their expansion into a news item. Even the routine of the Health Officer's work can be made interesting to the public if properly presented. Statistical reports of the deaths, births, and communicable diseases have their place in these columns, but should always be supplemented by other items of more human interest.

I started this work in Plattsburgh shortly after assuming the position of Health Officer, with the idea that the community should realize at all times that its water supply, its milk supply, and to some extent its food supply, was being looked after by the Board of Health and being kept up to a certain standard, believing, for instance, that an occasional statement throughout the year that the water examinations were satisfactory would gradually carry weight so that if it became necessary at any time during the summer to advise the boiling of drinking water, as a prophylactic against a possible epidemic, that it would be less liable to cause panic than the old way of completely ignoring such a factor as the water supply until it was necessary to publish a notice advising the public to boil their water. Under the latter circumstances the most usual thing was that a rumor would start that there had been several cases of typhoid and often times a number of deaths. Of course, sensation is always welcomed by the newspapers, balanced on the other hand by the fear of disturbing business conditions in the community. This latter was the condition met with recently in some of our communities when it was desired to make a frank statement in regard to smallpox.

A few examples of the sources of the copy for a local public health column are. Complaints received, constructive work going on, the application of general movements being advertised at the time, such as Child Welfare Week, to local conditions, or the utilization of startling news items, like the Nome episode, as an object lesson. In our publicity work in Plattsburgh, we have endeavored to keep away from the general news items, tuberculosis, cancer prevention, etc, except in so far as we could make a local application of them. We have not attempted to compete with the boiler plate, health news, or the State Department's publicity work. Practically all of our articles have been either in reference to some particular local condition or when of a

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 13 1925

general character, written purely from the public health point of view. Thus, in an article on tonsillitis, the prevention and particularly the means of preventing its spread to others were stressed and the matter of treatment taken up only in a very general way with the advice to consult one's family physician.

A few specimen topics of articles in the Plattsburgh papers under the auspices of the Board of Health follow

Toxin-antitoxin Work

Clean-Up Week

Garbage Disposal

Milk Inspection, followed by advice on the proper care of milk in the household after delivery

A series on the commoner contagious diseases and reporting to the Health Officer in cases where no physician is employed

The occurrence of a case of typhoid fever on a dairy farm near Plattsburgh, commend-

ing the owner for promptly reporting the case himself, and stopping the sale of his milk.

The putting of kerosene in milk bottles by householders

A series on Rickets, pointing out the activities of the Child Welfare Clinic

A series on the activities of the State Department of Health

In addition to using the column allotted for us, we have at times written editorials and at other times suggested material for editorials to be written up by the newspaper staff, all of which has been done with a great spirit of cooperation by the newspaper men. I feel that today, as a result of a little over a year's effort along these lines, that the people of Plattsburgh appreciate what their Board of Health is trying to do and are ready to cooperate at all times, further, that they have acquired a feeling of confidence in the Board which may be of great value to us, should an emergency arise or epidemic threaten.

## Deaths

BUTSCH, JOHN LOUIS, Buffalo, Johns Hopkins, 1912, Fellow American Medical Association, Fellow American College of Surgeons, Buffalo Academy of Medicine, Buffalo Surgical Society, Member State Society, Associate Physician Millard Fillmore Hospital. Died September 6, 1925

## EVIDENCES OF MEDICAL PROGRESS

Progress in the practice of medicine in New York State has been continuous although without spectacular featuring. It has been so gradual and slow that a busy practitioner who does not inform himself of what his confreres are doing may continue in the successful practice of methods of a quarter century ago without being deeply affected by the progress. But if that same practitioner should attend a third or fourth year class in a medical school or the rounds of a large hospital service with the chief, he would find that he must pass many milestones of progress before he reaches the standards of the up-to-date practice of medicine. The observant doctor can appreciate the progress of medicine in the community from year to year.

In what does progress in medicine consist?

One standard of measurement is the amount of new discoveries in a given time.

The discovery of new basic principles and the development of their application to patients constitute the science of the practice of medicine. Progress in medical science is the result of patient research by a limited number of gifted investigators in endowed laboratories, and a few clinical observers who record the histories of their cases with great care and truthfulness. All medical progress depends on these few who work along original lines. Their reports are recorded in special journals such as the Archives of Internal Medicine. These original workers set the ideals whose infiltration into the consciousness of general practitioners takes months or years.

While the science of medicine is made by a

few research workers, the standard of the art of medicine, or the practical use to which facts of scientific medicine is put, is the average practice of the doctors of a community. The sea of medical knowledge may advance in waves or in a swelling tide. Some doctors ride the foremost crest of every incoming wave that beats on the shore of ignorance, and when the wave breaks, they fall back with the receding undertow, but soon bob up on the crest of the next medical fad.

Medicine also advances like a rising tide, and we can measure its progress by the extent to which it reaches the great mass of general practitioners. A reliable test of the art of medicine in any community is the knowledge and skill that is shown by a representative number of doctors chosen at random. Suppose we choose the treatment of diabetes as the test. How many doctors can give insulin intelligently? How many can interpret the chemical findings which are the sure guides in the art of giving insulin? The tide of knowledge in the treatment of diabetes is rising but it has by no means reached all practitioners of medicine. Unmistakable evi-

dences of the rising of the tide of medical progress are seen everywhere in New York State. The State Medical Society has adopted graduate education as one of its major activities and the response of the county medical societies has been commendable. The membership of the State Society is composed principally of general practitioners of medicine and it is the family doctor on whom falls the burden of diagnosing and treating most diseases which fall upon suffering humanity. He wishes to know the short cuts in the practice of the medical art, how to examine a patient, and to know the outstanding diagnostic points of a sickness, and the approved methods of its treatment. He can make little or no use of fine points of pathology, or the history of a disease—he wants to know how to recognize it and cure it.

This is the kind of information which the Committee on Public Health and Medical Education will try to bring within the reach of the members of the county societies throughout the State. The fact that it is offered to the doctors is itself evidence of substantial progress in medicine.

## GRADUATE EDUCATION PLANS OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

Graduate education is making progress. That the State is ready for it, there is no doubt. Here and there of course we find skepticism and listlessness, and the inertia which so many of us enjoy, but everywhere there is a fine spirit of helpfulness.

The Committee on Public Health and Medical Education and the Special Committee on Graduate Education have met in Albany and New York, and are organized and functioning as a Joint Committee.

Surveys have been made and reports are constantly coming in from all the Districts of the State. Our immense amount of correspondence and a steady accumulation of information has resulted in the development of a comprehensive state-wide file which grows more valuable day by day.

Questionnaires have been sent to every county in the State. (See page 941.) The Committee tried to reach the County Committee on Medical Education or Public Health, where there was one, or the secretary of the County Society. Returns have been slowly coming in, but the questionnaires have invariably been carefully filled out.

A sub-committee is considering the whole question of graded courses. They are not as yet ready to report.

The State Department of Health is actively cooperating with its committees and has already provided speakers for meetings arranged

by the committees and county societies. Requests for the lectures in obstetrics and pediatrics are coming in so rapidly that there is some danger that we will be unable to meet the demand without severely taxing the resources of the State Department of Health. Already Chemung, Franklin, Rensselaer, Jefferson and St. Lawrence, Steuben, Allegany, Wyoming, Orleans, Wayne, Delaware and Washington have said that they are ready for these courses.

The great medical schools of the State are interested and willing to help. They have ready assets in their corps of teachers, some of whom at least will be willing to lend their services to the cause. This would be a great help. The same principles are involved in teaching clinical medicine in the field, as in giving instruction in the laboratory sciences. Good teachers are always active workers and so we hope they will enlist.

The Committee hopes for the loyal support of the entire profession. Everyone must help. The State is ready for graduate education. The task however is a tremendous one. The State is large, courses must be arranged, and willing workers assigned to counties, often far removed and perhaps difficult of access. The weather and the season of the year must be considered. Much money will be needed, and more than anything else, time. Time and cooperation will make everything possible.

Counsel, Medical Society of the State of New York

## LUMBAR PUNCTURE—PARALYSIS—DEATH

The plaintiff's decedent, a man of about forty years of age, called upon the defendant for the performance of a lumbar puncture, which was done at the doctor's office, and about 28 c c of clear fluid withdrawn. A local cocaine anaesthesia was used. In the performance of the puncture a small trocar was inserted into the spinal canal and the fluid withdrawn, no difficulty being experienced in entering the spinal canal and there being no bleeding. Upon the day following the puncture there was no evidence of infection at the site of the puncture, no temperature nor inflammatory condition observed. The patient lived about twenty miles from the doctor's office and after the puncture traveled to his home. The puncture was performed at about one o'clock p. m. At five o'clock of the following morning, seventeen hours after the puncture, the patient had evidences of paralysis. Under the microscope no blood was observed in the spinal fluid. Very shortly after the completion of the puncture the patient complained of severe pain in his left leg and required the administration of an opiate. On the day following the performance of the puncture the doctor saw the patient at his home, at which time there was a complete paralysis of both legs without sensory disturbances. There was also a retention of urine. The defendant advised hospital care for the patient and was to receive word from the patient's wife in this connection. Upon the second day following the puncture he communicated with the patient's home and was advised that he had been removed to a hospital under the care of another physician. The defendant communicated with the physician who was then treating the patient and was advised by said physician that about a year previously he had had the patient under his care for a condition which he believed to be paresis, and that the patient had suffered a complete mental breakdown, became unmanageable and required institutional care. The defendant was also told by the physician then attending the patient had been previously treated by this physician for syphilis, both intravenously and intraspinally. Nine days after the spinal puncture the defendant, in consultation with another physi-

cian, saw the patient at the hospital, at which time it was found that he had a complete paralysis of the lower extremities without sensory disturbances. The patient was apparently quite ill with some type of infection. Upon examination of the chest the presence of rales and crepitant breathing in the left lung were discovered. Six days after this visit by the defendant to the patient, the patient died. An autopsy was performed upon the patient and the then attending physician advised the defendant that the findings upon the autopsy were that the cause of death was pulmonary embolus, that there was also phlebitis of the left leg, cystitis and brain syphilis, that there were no signs of injury or inflammation to the spinal cord, which was removed at the time of autopsy. The pathologist who performed the autopsy was of the opinion that the patient suffered a softening of the spinal cord as a result of his long-standing syphilis of the nervous system.

In an action to recover against the physician who performed the lumbar puncture for the death of the patient due to his alleged negligence in the performance of the puncture, it was charged that the defendant was negligent and careless in performing the lumbar puncture, causing a paralysis to the patient, from which he died fifteen days later. It was claimed that the negligence of the defendant consisted in his failure to await the result of a lumbar test before injecting into the spine of the patient certain harmful fluids and in that he made the spinal puncture at a point too high on the spine and contrary to the proper practice, that he also made the puncture too deep, and that as a result of the defendant's negligence the plaintiff suffered from transverse myelitis, cystitis, phlebitis and pulmonary embolus, causing the paralysis and subsequent death.

This action remained upon the trial calendar for some time. When about to be reached for trial, the plaintiff being unable to establish the allegations of negligence contained in her complaint, and being unable to prove that any act of the defendant was the competent producing cause of the death of the patient, a discontinuance was had of the action, thus favorably determining it in favor of the defendant doctor.

## CONTRACTION OF LEG DUE TO BURN

In this action, brought on behalf of a boy about three years of age, it was charged that one of the defendants in the month of February was engaged to attend him and to cure and heal certain burns on the body of the infant, and the second physician employed later that the physicians were careless and negligent in their treatment causing a contraction of the skin on the burned area which resulted in a shortening of the right leg of the infant causing him to walk with a limp.

On February 13, one of the defendants received an emergency call to attend the infant who had received burns when his clothes caught fire playing around a bonfire on the street. On examination it was found that about three-quarters of the abdomen was burned and a part of the right thigh, also burns on the neck and on both hands and arms. The burns were of a third degree nature. The abdominal burn extended from a little below the umbilicus to about eight inches on the thigh and involving the muscles. Carron oil and a sterile dressing were applied and the child ordered to bed. The physician advised the removal of the patient to the hospital which the parents refused to do. Proper instructions were given by the physician to the parents as to the care and attention to be given to the child. In the evening of the same day he again visited the patient at which time the child had a temperature of 105 which was caused by the burns. The child was also suffering physical disturbances. A sedative was prescribed. Upon the following morning, on removing the dressings the physician found that the tissues on part of the thigh and abdomen were becoming black, indicating death of the tissue. The burned area was also covered with a number of blisters which were opened with sterile scissors. Part of the dead tissue was likewise removed and the burns again dressed with sterile dressings. The physician continued to make daily visits to the child, examining and dressing the wound each time. The burned tissue continued to necrose which was removed with sterile instruments. The child was also given bicarbonate of sodium baths by the physician and wet dressings of bicarbonate of soda applied. Proper medication was prescribed to reduce the temperature which still remained high. The child was seen daily until March 23rd. After granulation started the use of carron oil was discontinued. The necrosis of the tissue did not cease until about the middle of April. The granulation did not begin to take place on the abdomen or thigh until about four weeks after the injury. To stimulate the granulation the physician used extracts of bismuth, zinc and a bland ointment. The necrosis of the thigh extended through the skin, fascia down to and

involving the thigh flexures. The necrosis ceased and the process of granulation continued until this physician was discharged from the case on March 23rd. To prevent the formation of a large mass of granulated tissue the physician had curetted the excess granulated tissue.

The father of the child frequently interfered with the care given by the physician and remonstrated with him for his procedure and the necessary curetting of the necrosed or excess granulated tissue. The father was frequently advised to remove the child to the hospital where better care could be given him and skin graft, splints and other treatment could be resorted to, also that the healing process would probably cause a contraction and impairment of the function of the leg. The father responded that he would not remove the child to the hospital and did not care what the result was so long as the child would live. At the time this physician was discharged from the case there had been no contraction of the leg.

On April 1st the father called at the physician's office, paid the bill and told the physician that the child was getting along all right and if further medical care was needed the father would call him. On April 4th the father called at the physician's office for treatment for himself. At that time this physician advised the father that he was going abroad and suggested the name of another physician in the event further treatment was needed for the child.

On April 5th the second physician was called to the patient's home by the first physician to assist him in treating the father. At that time he removed the dressing from the child and observed that the tissue was granulating. On April 7th the second physician visited the child, removed the dressings, washed the granulating tissue with bicarbonate of soda and applied silver nitrate along the edges to stimulate granulation. The child was seen by this physician for about two weeks, at first every day and later on about every other day. On each visit the granulated tissue was washed, disinfected and silver nitrate applied as necessary. At the time the second physician stopped calling upon the child the spot had been reduced from the size of a silver dollar to about the size of a quarter. The second physician was likewise discharged from further treatment of the child, the father telling the physician that he did not believe further treatment was necessary.

The plaintiff not proceeding with the prosecution of the action, a motion was made to dismiss the same for lack of prosecution, which motion was granted terminating the action in favor of both physicians.

# State Department of Health

## STEPS TAKEN TOWARD BETTER FACTORY WATER SUPPLIES IN NIAGARA FALLS

In investigating a case of typhoid fever at Niagara Falls recently, Dr. Edward Clark, district state health officer, discovered that the patient had drunk water at a manufacturing establishment where she was employed. This water came from Niagara River and was filtered at the plant, but no further purification treatment was applied. Dr. Clark took up the matter with the local health officer, Dr. E. E. Gillick, who sent a circular letter to each of the manufacturing establishments in the city which used raw water for commercial purposes. This letter

pointed out the responsibility of such establishments where this type of supply is used. The circular recommended that every employee should be notified of the danger, either by talks or lectures in the factory or by adequate printed notices conspicuously posted.

Following these measures, the company where the patient was employed has taken steps to have a pure water supply provided at certain taps where the filtered drinking water has hitherto been available.

## A NEW TYPE OF PUBLIC HEALTH EDUCATION

The following paragraph is an excerpt from an article entitled "A New Public Health Service," which appeared in the May 7 issue of the Boston Medical and Surgical Journal.

The Massachusetts General Hospital has taken a step that is perhaps unique for a general hospital by instituting a real campaign for the education of the public along health lines. This

health source consists of the periodical publication in the daily press of complete and authoritative articles by members of the staff dealing with matters of general and common interest. These articles appear and will continue for a time to appear, weekly in prominent Boston newspapers. Five have already been published, dealing with body mechanics, hay fever and asthma, varicose veins, basal metabolism and rickets.

## ITINERANT DIPHTHERIA CARRIER A PROBABLE SOURCE OF THREE CASES

According to a communication received from a district state health officer following his investigation of the death of a child from diphtheria, the family in which the child lived had been visited some time previously by a man who was discovered to be a diphtheria carrier. The report states that this man was unquestionably the

source of two other cases which occurred shortly after he had visited their families.

This man broke quarantine and was later traced to Castleton, Vermont, where he was again quarantined. He escaped a second time, and his whereabouts are now unknown.

## PHYSICIAN CALLED LATE—CHILD DIES

A recent report on a death from diphtheria of a nine-year old girl, received by the Division of Communicable Diseases, indicates that a physician was not called until two weeks after the child was taken ill.

Although the disease involved the pharynx, tonsils, nose and naso-pharynx, and the physician tried to impress the family with the serious-

ness of the case, the child was not kept in bed until the last twenty-four hours.

In this case the parents were doubly negligent—in their failure to call a physician until so late that antitoxin could be of no avail, and in allowing the child to be up and about, contrary to the physician's instructions.

## GLENS FALLS AMERICAN LEGION WANTS TUBERCULOSIS CLINIC

The American Legion of Glens Falls is taking an interest in public health. The organization has appointed a civic affairs committee of which Dr. Morris Maslon is chairman. This committee

has already notified the board of health, common council and Mayor that in their opinion a tuberculosis clinic should be held in the city at regular intervals.

# GRADUATE EDUCATION

## JOINT MEETING OF COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION AND THE SPECIAL COMMITTEE ON GRADUATE MEDICAL EDUCATION

A joint meeting of the Committee on Public Health and Medical Education and the Special Committee on Graduate Medical Education, was held on the evening of August 21st, in Albany. There were present Dr. Charles A. Gordon, Chairman, and Doctors Jennings, Weiskotten, Madill, Tinker, Friedman, Johnson, MacFarlane, MacDonald and Chandler. The Executive Officer and the Executive Editor were also present by invitation.

The meeting lasted over three hours, and was characterized by earnestness and efficiency, as it developed through the three stages of the collection of evidence, a general discussion of conditions and definite decision.

The first third of the meeting was devoted to reports from each District Branch regarding the attitude of the members of the County Medical Societies toward Graduate Education.

Dr. Friedman, of the First District Branch, reported that the Orange County Medical Society had already instituted monthly meetings with clinical programs, and that the other counties were deeply interested in Graduate Medical Education, and were ready to undertake courses.

Dr. F. D. Jennings, of the Second District, outlined the extensive Graduate Education work of Kings County, and the course in Pediatrics in Suffolk County, and described the plans for giving the course in other counties of the Second District.

Dr. Chandler, of the Third District, said that he found the sentiment entirely favorable toward Graduate Education, and that the doctors wanted instruction in the practice of general medicine rather than the specialties.

Dr. MacDonald, of the Fourth District Branch, said that his District was the farthest removed from medical centers, and that his colleagues wanted instruction in pathology and other groundwork subjects, that Graduate Education would benefit his section more than any other section of the State, and that October was a good month for classes. Dr. Madill described the courses in Obstetrics that had been developed in St. Lawrence and Jefferson Counties (see the August, 1925, issue of this Journal, page 876). Dr. Madill said the courses gave the doctors something that they could use in their everyday practice.

Dr. Weiskotten, of the Fifth District Branch, said that in the large towns where abundant hospital facilities were available, the doctors asked

for intensive instruction in a small number of subjects, while in small places the doctors asked for fundamental instruction in several subjects. But first of all, he found that the doctors wanted to meet good teachers. He found that the most enthusiasm for Graduate work existed among doctors remote from hospitals.

Dr. Tinker, of the Sixth District Branch, gave a detailed report of the attitude of the doctors in each county of his District, and said that the sentiment was in favor of Graduate Education. He suggested the advisability of the smaller counties combining with adjoining counties in the courses.

Dr. W. D. Johnson, of the Eighth District Branch, said that he had made quiet visits to several counties, and was carefully investigating the attitude of the doctors in his District. He suggested the use of the hospitals for teaching, and the promotion of joint meetings among the smaller counties.

The Chairman explained the relation of the State Department of Health to the Graduate Education plan of the State Medical Society and the system of Regional Consultants in Pediatrics and Obstetrics, and how the consultants would be available for teaching. The Chairman also mentioned other agencies which might co-operate with the State Medical Society.

The reports of the members of the Committee mentioned all the various forms of Graduate Education which had been already started, many of which are described on page 875 of the August Journal.

The members of the Committee then entered into a lengthy discussion of the general principles involved in the Graduate Education plan of the State Medical Society, and yet each speaker was brief and clear. Dr. MacFarlane outlined some of the courses which had been carried out by the Albany Medical School, and presented arguments in favor of courses that required intensive study. He spoke of his experiences in his work of last year.

Dr. MacFarlane also discussed the question of payment to the lecturers and instructors, and presented arguments that payment would be good for both the lecturer and the listeners, for what one got for nothing was not likely to be appreciated.

The doctor also suggested that the Committee prepare syllabi on a few subjects and offer them to County Societies. The syllabi should be on

clinical subjects and illustrated with cases supplied by members of the County Society and worked up in full as to histories and laboratory tests

There was considerable discussion on the points brought up by Dr MacFarlane

Dr Jennings said that his experience in Brooklyn had shown that the more fundamental the lecture the more popular will be the course, as is shown by the crowds of doctors attending the five o'clock lectures of the Medical Society of the County of Kings. Doctors need instruction in the art of practicing medicine. He said that older doctors would take the courses as readily as the younger ones, for the need is general. Medicine is growing so fast that only through continuous education can men keep up their work and get their patients well.

Dr Weiskotten discussed the obstetrical courses given the Jefferson and St Lawrence counties, and thought that similar courses in other counties would be valuable. The desirability of publishing the lectures in the Journal was discussed, and some thought that if they were published, some doctors might be satisfied to read them and would not go to hear the speaker.

The discussion centered principally around the question as to the extent of the instruction to be given. Some speakers thought it should be intensive and others thought it should be confined to fundamental subjects—and the proponents of each plan conceded the desir-

ability of carrying out the other scheme as well as their own.

The third part of the meeting was directed by the Chairman who suggested that the Committee go on record with definite actions on some of the subjects that were discussed. Resolutions were formally passed along the following lines:

1 The State Committee shall work through the County societies and district branches, and no course shall be given or offered except through one of these organizations.

2 The courses in Pediatrics and Obstetrics that have been proven successful shall be offered to the county societies as courses already available.

3 The Chairman was authorized to arrange for such clinical lectures as the Orange County Medical Society may request in continuation of the course already in operation.

4 The moving picture films on tuberculosis and gastric ulcer shall be offered to the District branches for use in their annual meeting.

5 The Chairman shall appoint a sub-committee to prepare short courses, and shall find out from the medical schools whether they would be willing to help or not.

The meeting of the committee was highly practical and definite procedures were formulated and standards set.

CHARLES A GORDON

*Chairman, Committee on Public and  
Medical Education*

## QUESTIONNAIRE ON GRADUATE EDUCATION

Dr Charles A Gordon, Chairman of the Committee on Public Health and Education, has sent the following questionnaire to every county society addressed to the secretary, or to the chairman of either the Committee on Public Health or on Education. (See editorial page 936)

### THE QUESTIONNAIRE

1 What is your County Society doing in the line of graduate medical teaching?

2 Has your Society a committee on "Graduate Medical Education"? If so, who is chairman?

3 Has your Society any plans, tentative or otherwise, with regard to graduate teaching?

4 What facilities exist in your county to conduct extension courses such as meeting places for lectures, lantern, motion picture machine, hospitals, etc.?

5 Are there geographical divisions in your county which make it difficult to assemble at a central place or which would make it necessary in any plan to provide for your Society in geographical groups? If so, what are they?

6 What in your opinion would be attractive to your members in graduate teaching?

7 Has your Society a Public Health Committee? Who is chairman?

8 How many physicians in your county? How many are members of the County Society? Are most of them in public practice? Under average conditions what would be the best months in the year for extension work? How often and at what time of day would lectures or clinics be best held?

9 Are there any medical societies of importance, special or otherwise, in your county aside from the County Society?

10 Have you any suggestions or queries with respect to graduate teaching or public health activities which you wish to submit to the committee?

11 Are there in your membership physicians who are able and would be willing to take teaching assignments? If so, please list them.

12 Should physicians of the County who are not members of the Medical Society of the State or New York be included?

# MEDICAL ECONOMICS

The revised By-Laws of the Medical Society of the State of New York in Section 56, says

"The Committee on Medical Economics shall consist of five members including the chairman. It shall keep informed on all matters affecting the economic status of physicians and shall investigate and report on such matters as it deems necessary."

Rather a large program for five new men but your Committee has been selected with the idea of geological distribution, willingness to work, and understanding of the problems to be studied, and consists of

Dr William Warren Britt, Tonawanda,  
Chairman

Dr Charles O Boswell, Rochester

Dr Nelson K Fromm, Albany

Dr Henry B Doust, Syracuse

Dr Arthur S Chittenden, Binghamton

Economics may be defined as the science that treats of the development of material resources or the production, preservation and distribution of wealth and of the means and methods of living well, for the state, the family and individual. It covers the field of man's activities in making a living and particularly the relations of people in organized society, where in one way or another they cooperate in their labors and share in the results. The study of economics is for the purpose of understanding these complex relations, discovering the general rules or principles upon which people naturally act in them, and thus involving a system of order and cooperation in business, social life and public affairs.

The principles of economics are based upon and tested by experience. They are an interpretation of the experience of society. Many economic questions have been in controversy for a long time and will remain unsettled for a long time because the conditions to which they relate are continually changing, but there are certain principles upon which writers who are entitled to be regarded as authorities are in accord and concerning which all who wish to be well prepared for the responsibilities of every day life and of good citizenship should be informed.

Your Committee, on looking over the vast quantity of questions affecting the economic status of physicians, decided to send a questionnaire to the president of each county society. Many counties do not have a chairman

of Medical Economics but it is the hope of your Committee that each county will soon arrange to have some one appointed to this position.

The following questions are submitted

The Nursing Problem

Workmen's Compensation

Harrison Narcotic Administration

Distribution of Rural Practitioner

Industrial Medicine

Periodic Health Examination

Free Dispensary Practice

What Other Question?

and each one asked to number these in the order of importance from the standpoint of his county, also to submit any question he considered of importance.

Replies were received from thirty-seven counties, of which eighteen gave the Nursing Problem as of first importance. As a special Committee was appointed by the president of the Medical Society of the State of New York to consider this question we will not consider it here.

The question receiving the next highest number of first votes was the question of Periodic Health Examination. This question your Committee feels is an important one and it is our hope that through the combined efforts of all the counties we may devise a standard blank that will be adopted by all.

The remaining questions, arranged according to their importance as revealed by the replies received, are as follows:

Workmen's Compensation

Distribution of Rural Practitioners

Harrison Narcotic Administration

Industrial Medicine

Free Dispensary Practice

Other questions submitted by different counties were

Compulsory Vaccination

Chiropractic and Cult Question

Medical Ethics

State or County Aid for General Hospital in Rural Communities

Cooperation of Rural Physicians for Better Diagnostic Methods

This will indicate the lines along which we will work. We need the help of every physician who has anything to say along these lines and invite your correspondence.

W WARREN BRITT  
Chairman, Committee on  
Medical Economics

# MEDICAL SURVEY

## MEDICAL SURVEY NO 15—CATTARAUGUS COUNTY

**EDITOR'S NOTE** The information contained in this Survey was supplied principally by Dr James A Taggart, President of the County Medical Society and Dr Myron E Fisher, Secretary, Dr John J Mahoney, District State Health Officer, and Dr S A Douglass, County Health Officer

**Statistics**—Cattaraugus County is next to the most western of the southern tier of counties of New York State It has an area of 1,343 square miles It is approximately square, and its surface is rolling Farming is the dominating industry, but much oil is produced in the southern part of the county Its population was 71,323 in 1920, and is slowly growing It contains two cities, Olean, population 20,506, in the southeastern section, and Salamanca, population 9,276 south of the center of the county It contains 16 incorporated villages of which only seven have populations of over 1,000 apiece The largest village is Franklinville with 2,015 population

The distribution of population in Cattaraugus County is as follows

In cities	29,782
In 16 incorporated villages	15,374
In strictly rural sections	26,167
	<hr/> 71,323

The population of the county is fairly evenly distributed over the whole county, except in the Indian Reservation and State Park which together occupy about two hundred miles of waste land in the south central part, south of the Alleghany River The city of Salamanca is located in the Indian Reservation, and the people pay rent to the Indians

Good roads reach to every part of the county, and travel is easy throughout the year

**Physicians**—The directory of the Medical Society of the State of New York lists 83 physicians in Cattaraugus County, distributed as follows

Olean	36
Salamanca	9
Rest of county	38
	<hr/> 83

But when the list is checked up only 68 are found to be actually engaged in the practice of medicine This gives a ratio of one doctor to every 1,050 inhabitants

**Medical Societies**—The Cattaraugus County Medical Society has 49 members This is 72 per cent of the number of physicians in active prac-

tice in the county, but it is only 60 per cent of the number listed in the Directory Since some not in active practice return their membership in the County Society, the percentage of 60 is probably the more nearly correct

The County Medical Society holds bi-monthly meetings in various parts of the County The attendance usually ranges below twenty

The physicians of Olean have an organization called the Medical Club with 14 members, most of whom take an active interest in the County Medical Society The Society has no set organization, but the members take turns as hosts by twos, alphabetically, and entertain the members at a supper which is followed by a scientific program which the hosts arrange The members of the Club who were interviewed expressed themselves as eager to assist in the wider field of the County Medical Society

Twenty physicians in Olean and Salamanca and the neighboring villages had taken a course of study which had been arranged by Dr F W Sears, District State Health Officer of the State Department of Health Half the class met in Olean and the instruction was repeated in Salamanca The two courses were given twice a week during April, May and June, 1924, and the instruction was similar to that given in the Watertown course which was described on page 877 of the August JOURNAL While the course was designed primarily for health officers, those who took it praised it highly and said that it was in reality a practical course in general medicine which was of great value to the men in their general practice of medicine

The members of the County Society have been interested in the Graduate Education plan of the State Medical Society, and in the Spring of 1925 they made tentative plans for lectures in pediatrics The broader aspects of Graduation Education were considered at the September meeting, and a Committee of five, with Dr William B Johnston, of Ellicottville as Chairman, was appointed to suggest a course of instruction and report at the next meeting of the society

**Hospitals**—There are three hospitals in Cattaraugus County as follows

Higgins Memorial, Olean	100 beds
City Hospital, Salamanca	25 beds
County Tuberculosis	50 beds
	<hr/>
Total	175 beds

This gives a ratio of 2.4 beds for every one thousand of population

The Higgins Memorial Hospital has medical, surgical, and obstetrical services, and is well equipped and conducted. It is an open hospital, and staff meetings are held monthly at 8 30 in the evening. It has a history clerk, a laboratory with an expert technician, and an efficient X-ray department, but no ambulance service. It maintains a nurses' training school with 30 pupil nurses who go to Cleveland for instruction in the specialties.

The Salamanca Hospital is a general hospital, and is supported by the municipality. An addition that will double the capacity of the hospital is already planned.

The County Tuberculosis Hospital is located on top of a mountain three miles south of Olean. The site was chosen on account of the opposition which was made to a site in a more accessible settled part of the County,—the same opposition which was universally met ten years ago but which is now almost absent.

About one-third of the cases in the hospital are sent by physicians, and one-third by public health nurses, while another third are sent as the result of tuberculosis clinics which are held in various parts of the County. An addition is planned to house twenty patients.

*Public Health Work*—The official public health work of Cattaraugus County is done by an official County Department of Health and 27 health officers who serve 44 districts. The 25 health officers outside of the two cities serve 41,000 people—an average of 1,650 people for each health officer. Sixty per cent of the doctors outside of the cities, and 33 per cent of all the doctors listed in the county are health officers.

Seventeen health officers are members of the County Medical Society, and 18 have taken a special course of instruction to prepare themselves for their work.

A county public health laboratory is maintained in the Olean City Hall, and has been patronized by every physician in the county during the past year.

A venereal disease clinic is conducted weekly in Olean, and the service will soon be extended to other parts of the county.

Tuberculosis clinics are held regularly in six centers of the county.

Mental hygiene clinics are also held regularly by experts from the State institutions in Gowanda, Sonyea, and Rome.

*Public Health Nursing*—The Cattaraugus County Department of Health has a staff of 15 nurses. Olean has five supported by the City Department of Health, the School Board, the Red Cross, and the Tuberculosis Association. Salamanca, Portville and Gowanda each has a school nurse. There are 23 public health nurses in the county.

*County Department of Health*—Cattaraugus County is unique in that it is the only county in

New York State that has a County Department of Health. The laws of New York State (Section 20-b of the Public Health Law) authorize the formation of a County Board of Health which shall employ a full-time health officer, public health nurses, laboratory technicians, and other experts, and to establish laboratories, clinics, health stations, and adopt other procedures for promoting public health. The local health officers remain in office, but they are largely under the supervision of the County Health Officer. The plan provides a unit sufficiently large to carry on clinics, education, and other lines of work which supplement the purely local activities of the health officials.

The Cattaraugus County Health Department was authorized by the Board of Supervisors as the result of an offer by the managers of the Milbank Fund to give material assistance in financing the project. The Board of Health consists of five members, two of whom are physicians. The professional staff consists of a health officer, two assistant physicians, a physician technician in charge of the County Laboratory, a supervisor of school hygiene, a lay manager of publicity and education, and fifteen public health nurses. The County is divided into six districts, in each of which a health center is maintained, with headquarters for the nurses and facilities for holding clinics.

At the outset the general plan of the activity of the County Department of Health was that of a demonstration of lines of work carried on impersonally after the manner of work in a big city like New York. Examinations of hundreds of persons were made indiscriminately, and great numbers of visits were made by the dozen or more public health nurses without previously consulting the family doctors. Emphasis was placed on the word "demonstration," with considerable neglect of the principle set forth by Dr George E. Vincent: "Every doctor a health officer" (See this JOURNAL, June, 1925, page 758).

In adopting this general plan of activity, the leaders in the Cattaraugus demonstration merely followed a plan which had been advocated for years by some of the leading public health workers whose experience had been gained in the congested foreign quarters of large cities. When the present County Health Officer, Dr Stephen A. Douglass, took office in January, 1925, the principle advocated by Dr Vincent was adopted, and the facilities of the County Department of Health were placed at the disposal of the doctors and the Medical Society.

The doctors of Cattaraugus County are aware of their privileges and duties in the practice of civic medicine, and they express a willingness to adopt Dr Vincent's principle of every doctor a health officer.

F O

# DISTRICT BRANCHES

## SECOND DISTRICT BRANCH

ANNUAL MEETING, HEMPSTEAD, TUESDAY, OCTOBER 13, 1925

The Second District Branch will hold a joint outing, dinner, and meeting with the Associated Physicians of Long Island, on Tuesday, October 13th, at the Hempstead Country Club, East Front Street, Hempstead

The business meeting of the two societies will be held at the Clubhouse at 4:30 P M. An important feature of this will be the report of the Committee on Graduate Medical Education

There will be a dinner at 6 P M, the cost of which will be \$4.00 per plate. Reservations can be made for the dinner by sending a check for this amount, before October 9th, to Dr. Lefferts

A McClelland, 2 Rector Street, New York City, enclosing self-addressed envelope

A Scientific Session will follow the dinner, opening with an address by Dr. Nathan B. Van Etten, President of the Medical Society of the State of New York, followed by an exhibition of the motion picture film, "Motor Functions of Stomach," and "Gastric Ulcer," prepared by the American Medical Films, Inc., under the direction of Lewis Gregory Cole, M D

Opportunity for the use of the golf links will be available during the day upon payment of the Greens fees

## FIFTH DISTRICT BRANCH

ANNUAL MEETING, MARCY STATION, N Y, FRIDAY, OCTOBER 9, 1925

Automobiles will be at the Utica Central Station to convey members to the Marcy Station

FRIDAY, OCTOBER 9, 1925

Morning Session—10 A M

Meeting Called to Order by the President—

Nelson O. Brooks, M D, Oneida

"Address of Welcome"—Richard H. Hutchings, M D, Utica, N Y

"Treatment of General Paralysis with Inoculation of Malaria"—Preliminary Report by Clarence O. Cheney, M D, and George L. Warner, M D, Utica

Discussion Opened by Eugene N. Boudreau, M D, Syracuse

"Diagnosis of Cancer of the Stomach with Special Reference to Acid Values"—I. Harris Levy, M D, Syracuse  
Discussion Opened by Clark J. Laus, M D, Syracuse

"Surgical Procedures in Acute Perforation of Peptic Ulcers"—Gilbert D. Gregor, M D, Watertown  
Discussion Opened by Hyzer W. Jones, M D, Utica

Luncheon, 1 P M—By Invitation of Richard H. Hutchings, M D, Superintendent of the Utica State Hospital

Business Session—2 P M

Remarks by the President of the Medical Society of the State of New York—Nathan B. Van Etten, M D, New York City

"Medical Publicity"—Frank Overton, M D, Patchogue, Executive Editor New York State Journal of Medicine

"Some Opportunities of the District Branch"—Joseph S. Lawrence, M D, Albany, N Y, Executive Officer, Medical Society of the State of New York

"Post-Graduate Medical Education"—Herman G. Weiskotten, M D, Syracuse, N Y, Member of the Committee on Public Health and Medical Education

"Relief Measures During Labor"—Henry W. Schoeneck, M D, Syracuse  
Discussion Opened by George H. Bonnefond, M D, Utica

The Higgins Memorial Hospital has medical, surgical, and obstetrical services, and is well equipped and conducted. It is an open hospital, and staff meetings are held monthly at 8 30 in the evening. It has a history clerk, a laboratory with an expert technician, and an efficient X-ray department, but no ambulance service. It maintains a nurses' training school with 30 pupil nurses who go to Cleveland for instruction in the specialties.

The Salamanca Hospital is a general hospital, and is supported by the municipality. An addition that will double the capacity of the hospital is already planned.

The County Tuberculosis Hospital is located on top of a mountain three miles south of Olean. The site was chosen on account of the opposition which was made to a site in a more accessible settled part of the County,—the same opposition which was universally met ten years ago but which is now almost absent.

About one-third of the cases in the hospital are sent by physicians, and one-third by public health nurses, while another third are sent as the result of tuberculosis clinics which are held in various parts of the County. An addition is planned to house twenty patients.

*Public Health Work*—The official public health work of Cattaraugus County is done by an official County Department of Health and 27 health officers who serve 44 districts. The 25 health officers outside of the two cities serve 41,000 people—an average of 1,650 people for each health officer. Sixty per cent of the doctors outside of the cities, and 33 per cent of all the doctors listed in the county are health officers.

Seventeen health officers are members of the County Medical Society, and 18 have taken a special course of instruction to prepare themselves for their work.

A county public health laboratory is maintained in the Olean City Hall, and has been patronized by every physician in the county during the past year.

A venereal disease clinic is conducted weekly in Olean, and the service will soon be extended to other parts of the county.

Tuberculosis clinics are held regularly in six centers of the county.

Mental hygiene clinics are also held regularly by experts from the State institutions in Gowanda, Sonyea, and Rome.

*Public Health Nursing*—The Cattaraugus County Department of Health has a staff of 15 nurses. Olean has five supported by the City Department of Health, the School Board, the Red Cross, and the Tuberculosis Association. Salamanca, Portville and Gowanda each has a school nurse. There are 23 public health nurses in the county.

*County Department of Health*—Cattaraugus County is unique in that it is the only county in

New York State that has a County Department of Health. The laws of New York State (Section 20-b of the Public Health Law) authorize the formation of a County Board of Health which shall employ a full-time health officer, public health nurses, laboratory technicians, and other experts, and to establish laboratories, clinics, health stations, and adopt other procedures for promoting public health. The local health officers remain in office, but they are largely under the supervision of the County Health Officer. The plan provides a unit sufficiently large to carry on clinics, education, and other lines of work which supplement the purely local activities of the health officials.

The Cattaraugus County Health Department was authorized by the Board of Supervisors as the result of an offer by the managers of the Milbank Fund to give material assistance in financing the project. The Board of Health consists of five members, two of whom are physicians. The professional staff consists of a health officer, two assistant physicians, a physician technician in charge of the County Laboratory, a supervisor of school hygiene, a lay manager of publicity and education, and fifteen public health nurses. The County is divided into six districts, in each of which a health center is maintained, with headquarters for the nurses and facilities for holding clinics.

At the outset the general plan of the activity of the County Department of Health was that of a demonstration of lines of work carried on impersonally after the manner of work in a big city like New York. Examinations of hundreds of persons were made indiscriminately, and great numbers of visits were made by the dozen or more public health nurses without previously consulting the family doctors. Emphasis was placed on the word "demonstration," with considerable neglect of the principle set forth by Dr George E. Vincent: "Every doctor a health officer" (See this JOURNAL, June, 1925, page 758).

In adopting this general plan of activity, the leaders in the Cattaraugus demonstration merely followed a plan which had been advocated for years by some of the leading public health workers whose experience had been gained in the congested foreign quarters of large cities. When the present County Health Officer, Dr Stephen A. Douglass, took office in January, 1925, the principle advocated by Dr Vincent was adopted, and the facilities of the County Department of Health were placed at the disposal of the doctors and the Medical Society.

The doctors of Cattaraugus County are aware of their privileges and duties in the practice of civic medicine, and they express a willingness to adopt Dr Vincent's principle of every doctor a health officer.

F O

physicians against incisions upon the palm or palmar surfaces of the fingers

Dr Williams gave an encouraging picture of the results of the use of insulin during the three years since it was discovered. While formerly children with diabetes might expect only a year or two of life, now with the use of insulin they

are able to lead normal lives and to grow as fast as other children. He also said that insulin stimulates the production of insulin in the body.

The papers were of great practical interest and value. Some were lantern slide talks, but those which were written will probably be published in this JOURNAL. F O

### THIRD DISTRICT BRANCH

President Charles P. McCabe and his associate officers carried out a highly successful meeting of the Third District Branch of the Medical Society of the State of New York, on Friday, September 25th, at Twilight Park, Haines Falls, Greene County. Seventy doctors were present.

The meeting place was in the heart of the Catskill Mountains, the air was unusually clear, the arrangements for the meeting were excellent, and all those in attendance were happy at the close of a perfect day.

The morning session was opened with an address of welcome by Dr Lyle B. Honeyford, President of the Greene County Medical Society to which Dr Charles P. McCabe, President of the District Branch, responded.

The morning scientific program consisted of a symposium on lesions of the stomach, led by Dr Charles Gordon Heyd of New York City, on Diagnosis, Dr Arthur Bassler of New York City, on Medical Treatment, and Dr Charles H. Peck of New York City, on Surgical Treatment. The speakers brought out points which were new and practical, and their papers will probably be published in an early issue of this Journal.

Dr Nelson K. Fromm of Albany discussed "Some Neurological Problems," and spoke on the principal points of differential diagnosis of the acute inflammations of the central nervous system.

The greater part of the afternoon session was devoted to a discussion of problems of the medical societies—State, Branch and County. Dr N. B. Van Etten, President of the Medical Society of the State of New York, discussed the major activities of the Society in detail in a happy way. Dr Joseph S. Lawrence, Executive Officer of the State Society, outlined a field of wider usefulness for the District Branches.

Dr George F. Chandler of Kingston, a member of the Committee on Public Health and Medical Education of the State Society, outlined the plan of graduate education which the Committee has to offer to the County Societies, and urged each society to choose a serious course and carry it out. He made a convincing plea for *clinical*, as distinguished from didactical instruction, by a comparison of medical instruction

with that of the state police, of which Dr Chandler was once commander. He said that the policemen who have had extensive courses in the best didactic instruction without experience were usually failures, while the men made good when they were trained in courses based on what they actually saw. The clinical method was highly successful in training policemen and it would be equally successful in training physicians. He said that the members of his committee were especially anxious to promote teaching by the discussion of actual cases.

A pleasing feature of the program was the exhibition of a moving picture film illustrating gastric peristalsis and gastric ulcer. This film was made by Dr Gregory Cole, of New York City, for the American Films Company. It is full of action and interest, and enables the doctor to visualize the movements of the stomach, both normal and abnormal, in a way that nothing else can do. This film is recommended to county societies for use in their graduate courses.

Dr McCabe had introduced a novel feature in District Branches by appointing Committees on Medical Education, Public Health Nursing, Membership, and County Society Programs, and these committees gave brief reports. Dr Andrew MacFarlane gave a more extensive review of the nursing situation throughout the State and suggested that two types of nurses be trained and recognized—the present Registered Nurse and the Domestic Nurse.

Dr Charles Rayevsky reported on County Programs and suggested that the social side of the programs be emphasized both at every meeting and at special meetings given over to social functions only.

Dr McCabe gave a practical demonstration of the points in Dr Rayevsky's report by making excellent arrangements for entertainment. About forty members had brought their wives, who were entertained at a bridge tea under the leadership of Mrs. E. A. Vander Veer of Albany. A dance was held in the evening under the management of Mrs. Redman, hostess of Twilight Inn.

Many of the members and their wives remained over night in order to enjoy golf and other sports on the next day. F O

## SIXTH DISTRICT BRANCH

ANNUAL MEETING ITHACA TUESDAY, OCTOBER 6, 1925

Address Nathan B Van Etten, M D, New York City, President Medical Society of the State of New York

"Infections and Mental Disease," William C Garvin, M D, Superintendent, Binghamton State Hospital

"Clinical Interpretation of the Wassermann Test," William Avery Groat, M D, Syracuse

"The Use of Sodium Iodide in Focal Infections," James W Wiltsie, M D, Binghamton

"The Accessory Nasal Sinuses," illustrated by specimens, Abram T Kerr, M D, Professor of Anatomy, Cornell University Medical School

"A Case of Chronic Juvenile Lenticular Degeneration" (Wilson's Disease, lantern slides, James W Papez, M D, Professor of Neurology, Cornell University Medical School, Ithaca

"The Influence of the Thyroid on Structure and Function in Sheep and Goats," motion pictures, Howard S Liddell, Ph D, Department of Physiology, Cornell University Medical School.

Lunch will be served in the Bank Auditorium Restaurant on the same floor, at \$1 00 per plate

The Ladies' Entertainment Committee will provide entertainment for visiting ladies

## THE SEVENTH DISTRICT BRANCH

The series of District Branch meetings was begun by the Seventh which held its meeting on Thursday, September 24th, in the Chamber of Commerce building, Auburn, with about sixty members in attendance, and the President, Dr William I Dean, of Rochester, in the chair

Two sessions were held beginning at 10 30 o'clock, and with an hour's intermission for luncheon in the same building with the meeting

An election of officers resulted in the following choice President, Dr Claude C, Lytle, Geneva, First Vice-President, Dr G Kirby Collier, Rochester, Second Vice-President, Dr Alfred W Armstrong, Canandaigua, Secretary, Dr John A Lichty, Clifton Springs, Treasurer, Dr Edward T Wentworth, Rochester

Dr N B Van Etten, President of the Medical Society of the State of New York, spoke on the activities of the State Society He paid a tribute to Governor Smith for calling a meeting of representative doctors to advise him regarding medical legislation, and spoke of the bright prospects in legislative matters this coming winter He said that the special committee appointed to write a medical practice bill had met every two weeks since June, and had produced a bill embodying some of the same features which relate to the practice of law

Dr Van Etten told of the need of a more extensive plan of group insurance owing to the great amount of litigation brought against doctors, and said that he would not dare practice medicine without an indemnity policy A new plan will probably be presented to the members in the early future

The Doctor also dwelt at considerable length upon the work of the Committee on Public Health and Medical Education, and urged the leaders in the County Medical Societies to take advantage of the courses offered by the State Society He

also discussed the nursing problem, periodic health examinations, and the care of the insane and feeble-minded

Dr John M Swan, of Rochester, gave a brief description of the organization of the New York State Society for Cancer Control and urged the county societies to promote the work, especially in educating both physicians and laymen

Dr Edward T Wentworth discussed bonesetters and chiropractors from a practical point of view

The purely scientific part of the program consisted of five papers as follows

"The Treatment of Tic Douloureux," Ward Williams, M D, Rochester

"The Treatment of Scarlet Fever with Convalescent Blood Serum," Perry A. Bly, M D, Rochester

"Ureteral Stricture," Alfred K Bates, M D, Auburn

"Infections of the Hand," Harry R Trick, M D, Buffalo

"Results Obtained from Long-continued Use of Insulin," John R Williams, M D, Rochester

Dr Bly described the excellent results which had been attained in the Rochester Municipal Hospital by the use of injections of either whole blood from recovered cases, or serum from the blood or the Dochez serum

Dr Bates described some cases of stricture of the ureter in which the symptoms suggested gall bladder inflammation or appendicitis He urged that physicians bear ureteral stricture in mind in every uncertain abdominal condition

Dr Trick showed charts of the various seats of inflammation of the hands, and described the standard treatment for each This is a subject of great interest to every doctor on account of the deformity which is likely to result from improper treatment Dr Trick especially warned

his two daughters, who joined the fraternity at the dinner hour

After a pleasing dinner served in the Elks' dining room, a business session was held

Dr Shaw extended a personal invitation to all medical men to come to an "Old Fashioned Clam Bake," to be given by The Albany Country Club on Wednesday, September 16th, sports of all kinds in the afternoon, and the dinner at 6 30 P M, followed by a dance in the evening The entire program being under the supervision of the Albany County Medical Society

A discussion of training schools for nurses followed. A resolution was adopted and directed to be sent to the State Board of Education urging a modification of the present ruling whereby

small hospitals have been crowded out of the right of training nurses

The subject of holding a series of clinical lectures each week for six weeks was discussed and left for a special committee to report on

After some general business the meeting adjourned

The following members were in attendance. Drs H L Cruttenden and A H Bissell, of Cooperstown, J Perry Horle, of Fly Creek, F E Bolt, of Worcester, E C Winsor, of Schenectady, F L Winsor, of Laurens, B F Bishop, of Garrettsville, L C Warren, of Franklin, D H Mills, M E Brownell F H Marx, L S Lang, W S Dart, J C Smith, Stanton Hendricks, R D Champlin and A H Brownell, of Oneonta

---

## THE ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES

HOTEL WILSDORF-ASTORIA, NEW YORK, OCTOBER 8TH TO 10TH

The programme will include visits to West Point, Ellis Island, the Naval Hospital and Medical Supply Depot in Brooklyn, the airdrome at Mitchel Field on the day of the Pulitzer race, the Rockefeller Institute and various hospitals, and a review of and demonstration by

the 102nd Medical Regiment of the 27th Division

Physicians who are serving or have served in the Army, Navy, Marine Corps, the Reserve, the National Guard or the Public Health Service are eligible to membership

---

## NEW YORK AND NEW ENGLAND ASSOCIATION OF RAILWAY SURGEONS

The 35th annual meeting of the New York and New England Association of Railway Surgeons is to be held at the Hotel Commodore, New York

City, on November 5th and 6th, the meetings to be on the 5th, followed by Clinics in New York Hospitals on the 6th

---

## TRAVEL STUDY CLUB OF AMERICAN PHYSICIANS

The Travel Study Club of American Physicians at its ninth Annual Reunion, held May 26th in Atlantic City, re-elected Dr Louis Livingston Seaman and Dr Richard Kovacs of New York respectively as President and Secretary-Treasurer, Dr Edward B Heckel, Pittsburgh, Pa, Dr J P Lord, Omaha, Neb, and Dr F H Albee, New York City, as Vice-Presidents

The Travel Study Club has decided on a 1926 study tour to London, Paris, Switzerland, Munich, Vienna and Berlin Participation in this tour will be limited in number and restricted to members and medical friends recommended by them, thus endeavoring to insure comfort, congeniality and equal opportunities for study on this tour

## MEDICAL SOCIETY OF THE COUNTY OF CATTARAUGUS

The Fourth Bi-Monthly meeting of the Medical Society of the County of Cattaraugus was held in Delevan, N Y, September 8, 1925

There was a fairly good attendance and those who were present were well paid

The matter of graduate attendance was brought up and referred to a committee of five members to investigate and report to the society

Two papers were read

One by Dr Byron D Bowen, of Buffalo, on "The Present Day Problems of Diabetes"

The Doctor presented the essential facts in regard to the disease in a very interesting and instructive manner

Dr Nelson G Russell, of Buffalo, presented the subject of "Treatment of Cardiac Disease" in a very practical way

Both papers were of a very high order and were well received by those present It is certain that no more instructive or practical lectures could be presented by any one than were given here and by well-known men

MYRON E FISHER.

## ROCKLAND COUNTY MEDICAL SOCIETY

The regular quarterly meeting of the Rockland County Medical Society was held on the afternoon of September 23rd at Letchworth Village with the Vice-President, Dr R F Sengstachen in the chair, and twenty members present

Dr George A Leitner, member of the special committee that was appointed by the State Society to write a new practice of medicine bill, reported that the committee had met about every two weeks and was almost ready to announce the bill He suggested that the Society invite the two candidates for assemblyman to attend the special obstetrical meeting of the Rockland County Medical Society, which will be held some time in October, and that the physicians of the county make every effort to enlighten the candidates regarding the matters of medical legislation These suggestions were put in the form of a resolution, and unanimously carried

The speaker of the day was Dr Joseph Globus, Adjunct Neurologist to Mt Sinai Hospital, New York City His subject was Diagnostic Features of Various Forms of Paralysis with particular reference to brain tumor and encephalitis Dr Globus gave a simple, clear outline of the various sites of the lesions causing paralysis, and said that if the lesion was in the forebrain, the paralysis would be of

the spastic type with firm contractures of the muscles in the older cases If the lesion was in the midbrain, the paralysis was of the rigid type with a jerky motion when the limb was forcibly moved If it was in the hind brain, or cord, the paralysis was of the flaccid type A fourth type of paralysis was that in which the lesion was in the muscle cells themselves

Dr Globus chose cases from the institution which illustrated perfectly the various types of paralysis, and those who saw this demonstration will always have a vivid idea of the meaning and recognition of spasticity, rigidity, intention tremors, incoordination, and other neurological conditions

After hearing the lecture, the members present at the meeting heartily agreed with Dr Globus when he said, "While neurology was formerly concerned principally with post-mortem states, it is now a very live specialty, full of diagnostic and therapeutic possibilities"

Dr Globus made the subject so simple and clear that its practice would appeal to general practitioners

After the meeting, the doctors were the guests of Dr C S Little, Superintendent of Letchworth Village, at a supper—an annual event to which the physicians look forward with pleasure

F O

## OTSEGO COUNTY MEDICAL SOCIETY

Quarterly Meeting of the Otsego County Medical Society was held at the Elks' Home, Oneonta, N Y, on September 8, 1925

In the absence of Dr Swanson, Dr A H Bissell was made Chairman of the meeting

The afternoon session was given over to the subject of Malnutrition and Infant Feeding Dr Henry L Shaw, of Albany, President of the Albany County Society and Pediatrician for St

Margaret's and St Peter's Hospitals of Albany, was the speaker for the occasion Dr Shaw gave a very interesting history of infant feeding and a very helpful discussion of the latest views along that line He closed his address with a humorous sketch as to how children continued to grow in spite of the variety of foods and fancies that had been indulged in during the ages past Dr Shaw was accompanied to the city by

his two daughters, who joined the fraternity at the dinner hour

After a pleasing dinner served in the Elks' dining room, a business session was held

Dr Shaw extended a personal invitation to all medical men to come to an "Old Fashioned Clam Bake," to be given by The Albany Country Club on Wednesday, September 16th, sports of all kinds in the afternoon, and the dinner at 6 30 P M, followed by a dance in the evening The entire program being under the supervision of the Albany County Medical Society

A discussion of training schools for nurses followed. A resolution was adopted and directed to be sent to the State Board of Education urging a modification of the present ruling whereby

small hospitals have been crowded out of the right of training nurses

The subject of holding a series of clinical lectures each week for six weeks was discussed and left for a special committee to report on

After some general business the meeting adjourned

The following members were in attendance Drs H L Cruttenden and A H Bissell, of Cooperstown, J Perry Horle, of Fly Creek, F E Bolt, of Worcester, E C Winsor, of Schenectady, F L Winsor, of Laurens, B F Bishop, of Garrettsville, L C Warren, of Franklin, D H Mills, M E Brownell, F H Marx, L S Lang W S Dart, J C Smith, Stanton Hendricks, R D Champlin and A H Brownell, of Oneonta

# THE DAILY PRESS

The daily papers during the first fortnight of September carried whole pages about a murder by a young man whose homicidal trend was well known to his parents and to the legal authorities. Many columns were printed regarding responsibility for the freedom from restraint which was allowed to the young man, and as usual in such cases, an office-holder—in this case a doctor in a State hospital—was made a belated sacrifice in order to appease public opinion.

Mental pathology is one of the newer branches of medicine. Its field is almost as broad as that of the body, and the literature of abnormalities in morals and behavior is as great as that in medicine and of the physical body. The field is so vast and intricate and new that few general practitioners attempt to comprehend it or put it to practical application.

If physicians are not psychiatrists, much less do laymen understand the subject of mental abnormalities. Even educated people profess to be able to judge the mental state of a patient by a few moments of conversation with him. The parents or relatives of a maniac who has just been committed to a hospital see him clothed and contrite, and are softened by his expression of repentance and his promises to be good. The parents do not realize that the patient is simply on his "company" behavior, and will be the same bad boy again when he goes home. The treatment that the patient needs is to stay in the hospital for weeks or months where he will act as a polite guest (another name for an unconscious yet potent form of discipline) until a normal working of the brain becomes a fixed habit. But the relatives can "see for themselves" that the patient is in his right mind, and so they go to law and take him home, and then when he commits arson or murder, they say that they were not properly informed regarding his condition.

The ultimate responsibility for releasing the insane lies with lawyers, judges, and juries, and their actions are based on their own inadequate knowledge and of psychiatry, or on public opinion, which is still more inadequate. If the hospital doctors refuse to sanction a release, there must be a trial and the presentation of evidence—and the lawyer on the bench is the judge of the reliability of that evidence. (See Mr. Whiteside's article in the September Journal.) If the evidence shows merely some queer action, the Judge may answer that every man does queer things sometimes. A witness who has seen an assault committed by the insane person is likely to have an exceedingly poor memory on the witness stand from fear of revenge if the insane man is released and will may the witness have fear, for there will be none to protect him.

The staffs of the State Hospitals are conducting clinics in mental hygiene, which is a euphonious name for incipient insanity or mental defects. The staff of the Utica State Hospital has conducted an extensive series of clinics in the Mohawk Valley with such success that one-fifth of the inmates of the hospital have come there voluntarily for treatment at a stage when they can probably be cured (see this Journal, August, 1924, page 813). This means that a still greater number of cases of incipient insanity are treated and cured at the clinic without the necessity of their going to the Hospital.

The kind of work which is done in the mental hygiene clinics is similar to that which family doctors could readily do, and which they will be doing within a few years. Dr. Gordon, the Chairman of the Committee on Public Health and Education of the Medical Society of the State of New York, has made inquiry among the Superintendents of the State hospitals regarding the practicality of giving courses in "office psychiatry" to general practitioners of medicine. The response is that such courses are needed and that the members of the staffs are willing to give them, and are confident that doctors can readily grasp the principles of psychiatric methods of diagnosis and treatment. However, they are not enthusiastic over the response of the doctors to invitations to attend clinics or to refer cases to them. Yet this lack of response is by no means discouraging. The idea is new, and its usefulness had first to be demonstrated. That has been done, and now the next step is to popularize it among the doctors.

Possibly one way to obtain the interest of doctors is to prepare and print a series of articles on office psychiatry. We have already had the offer of some articles along that line.

The discussion in the daily papers to which we referred at the beginning of this article has focussed popular attention on the practice of clinical psychiatry, and demonstrated the need of popular education in the subject. But the subject is exceedingly broad and far-reaching, and cannot be taught in a day or a year, or even in a decade.

If doctors do not take up the subject of mental hygiene, lay organizations will, just as they have taken away a good part of the leadership in tuberculosis control.

There must be an orderly evolution or development of instruction in psychiatric subjects. First comes the development of both the science and the art of psychiatry by the leaders. Next is the instruction of the doctors, and when the doctors are ready to practice psychiatry they will soon educate the people.

# BOOK REVIEWS

**ELEMENTS OF PHYSICAL BIOLOGY** By ALFRED J LOTKA, M.A., D.Sc. Octavo of 460 pages, illustrated Baltimore, Williams and Wilkins Co., 1925 Cloth, \$5.00

This book is an ambitious and scholarly attempt to introduce a new member into the galaxy of sciences. How far the author has gone, how well his task has been accomplished, cannot be ascertained by any mere desultory or casual perusal of the work.

The contents are divided into four parts. Part I takes up General Principles, Part II, Kinetics, Part III, Statics, Part IV, Dynamics.

The author has brought to his task the calm, detached and impersonal viewpoint of the philosopher, the logic of the accomplished mathematician, and an unusual erudition. He displays a singular knowledge of the fundamental sciences, chemistry, physics and biology.

The average professional reader will find the work on this account dull and tiresome, but to the man whose knowledge is broader a rare intellectual feast awaits his perusal of this book. F B D

**SERUM DIAGNOSIS OF SYPHILIS BY PRECIPITATION** Governing Principles, Procedure and Clinical Application of the Kahn Precipitation Test By R. L. KAHN, M.S., D.Sc. Octavo of 237 pages Baltimore, Williams and Wilkins Co., 1925 Cloth, \$3.00

The work is well presented. The arrangement of the book is good. The reader receives a clear idea of the fundamental principles essential for the development of the test, with definite enlightenment from comprehensive experiments and tables. Chapter XX leaves some doubt in the mind as to the value of the test for spinal fluids. The initial treatment of the fluids in precipitating out the globulins makes one feel that the Wassermann Test is less time-consuming and quite as reliable.

The author's deductions as to the efficacy of the test are fair, but as a general conclusion we should say that the Kahn Test has no decided advantage over the Wassermann Reaction although it provides a valuable check on the latter. We are pleased to recommend the work as a scientific, instructive and carefully written volume and the Test as a valuable routine to be incorporated in every pathological laboratory. R E. CAMPBELL.

**LUMBAR PUNCTURE.** Its Anatomical and Physiological Relations. Technique. Methods of Investigation. Diagnostic Value and Therapeutical Applications. With an Appendix on Encephalography and Puncture of the Cisterna. By MARTIN PAPPENHEIM, M.D. Translated by George Caffrey. Octavo of 248 pages. New York, William Wood & Co., 1925. Cloth, \$5.00.

This volume is of much interest to both clinician and laboratory worker. In discussing technique, the author prefers the lateral position, the patient lying preferably on the right side. Novocaine anesthesia is preferred. 1/2 per cent solution of a wheal being produced and some novocaine injected through this, after having introduced the needle vertically to a depth of about 2 cm. Puncture is preferred exactly in the median line rather than from a point to the side as there is believed to be less risk of injury to the fibres of the cauda and bleeding is less liable to occur.

Among the conditions in which lumbar puncture is stated to be certainly attended with danger are the presence of tumors of the brain in the region of the posterior cranial fossa, internal hydrocephalus, general edema of the brain, and recent apoplexy.

Over one hundred pages are devoted to the technique of the various laboratory procedures. The closing chapters are devoted to a discussion of the diagnostic and prognostic import of lumbar puncture and its therapeutical applications, with an appendix on encephalography and puncture of the cisterna cerebello-medullaris.

W. E. McCOLLUM

**CLINICAL PSYCHOLOGY** By LOUIS E. BISCH, M.D., Ph.D. Octavo of 346 pages, with illustrations. Baltimore, Williams and Wilkins Co., 1925. Cloth, \$3.00.

In this book there is collected a considerable mass of information relative to the recognition and management of mentally atypical children. The text is well exemplified by sixty case histories. The subject matter covers a much trodden field, but the manner of presentation should render the book useful to the various classes of laymen who are in need of information on juvenile psychiatry. FREDERIC DAVRAU

**HYGIENIC FUNDAMENTALS OF FOOD HANDLING** By CHARLES THOM and ALBERT C. HUNTER of the Microbiological Laboratory, Bureau of Chemistry, U.S. Department of Agriculture. 228 pages, illustrated. Baltimore, Williams & Wilkins Co., 1924. Cloth, \$3.00.

The title well describes the scope of the book. First taking up the general considerations of wholesomeness and fitness of food, its preservation, spoilage, and food poisoning and infections, the authors take up in later chapters the individual problems pertaining to each group of foodstuffs. It is a work which will be appreciated best by those most interested, that is those concerned in food handling industries, public health workers and economists.

Although the work itself covers a limited ground only, many bibliographical references are supplied so that one may be able to follow a given topic much more extensively if he desires. E. H. MARSH

**THE DETERMINATION OF HYDROGEN IONS** An elementary treatise on the hydrogen electrode, indicator and supplementary methods with an indexed bibliography on applications. By W. MANSFIELD CLARK, M.A., Ph.D. Second Edition. Octavo of 480 pages. Baltimore, Williams and Wilkins Co., 1925. Cloth, \$5.00.

This is an elementary yet exhaustive treatise on the principles and methods for the determination of hydrogen ions. The author has gained wide recognition as a leader in research on H-ions and is an authority on this subject. It is interesting to note that he began his work in the laboratories of the Dairy Division of the U.S. Department of Agriculture.

The book includes a general discussion of electrolytic dissociation and H-ion concentration, the theory and use of indicators in colorimetric determination, the theory and use of the electrometric method, a chapter on various supplementary methods, applications and bibliography. Under applications it is interesting to note the wide variety of uses, including physiology, pathology, bacteriology, pharmacology, industrial chemistry and agriculture. The bibliography is very extensive.

While displaying a meticulous care in his use of words, the author has presented an involved subject in a remarkably clear style. The worker will find here a rare combination of clear exposition of general principles, minute directions for procedure and caution against sources of error. E. B. SMITH

**LA REACTION DE FIXATION DANS LA TUBERCULOSE PAR ARCHILLE URBAIN** Preface De A BESREDA, Professeur A l'Institut Pasteur Masson et C, Editeurs Libraries De L'Academie De Medicine, 120 Boulevard Saint-Germain Paris, 1925

The Author of this work is known universally as an authority in the study of Immunity, Allergy, Serology and Complement Fixation, in tuberculous infection and disease. This work represents a very complete study of the varying phases in the complement fixation in tuberculosis, and of the interpretation of the same. He is careful to point out how invaluable an aid the reaction is when supplementing the data we acquire in any given case, by use of our physical senses—observation, auscultation etc. He regards it as rather a more precise method, perhaps, than any other, though admitting its interpretation must be based on a consideration of all the data acquired. He feels that complete accord is necessary between the laboratory and the clinic, properly to appraise and weigh the evidence. This work represents a truly valuable contribution to the Immunological Studies of Tuberculosis. FOSTER MURRAY

**AIDS TO SURGERY** By JOSEPH CUNNING, M.B., B.S., F.R.C.S., England, and CECIL A. JOLL, M.S., Lond., F.R.C.S., England. Fifth Edition. William Wood & Co, New York, 1924. Price, \$1 50

This quiz compend of 434 pages first appeared in 1904, since then it has been reprinted fifteen times and reedited four times. In structure this pocket manual conforms to the usual form of students' aids but has rather more of the virtues and less of the defects than most quiz compends. In this fifth edition Mr Joll has brought the subject matter up to date. JAMES L. COBB

**PHYSICAL DIAGNOSIS** By W. D. ROSE, M.D., Lecturer Physical Diagnosis and Associate Professor Medicine, University of Arkansas. Fourth Edition. Three hundred and nineteen illustrations. C. V. Mosby Co., St. Louis, 1924. Price, \$8 50

The need of a fourth edition of this book on Physical Diagnosis proves its value. For those who have not studied the earlier editions the reviewer would state that this is an excellent work which presents the subject matter accurately, thoroughly, clearly, completely and in an interesting manner. The many illustrations are clear, instructive and add much to the value of the book. The previous editions have been so carefully presented that there has been but little need of additions in this fourth, however, the author has made some minor additions to the subject matter of the circulatory system. H. M. M.

**MANUAL OF PSYCHIATRY FOR THE MEDICAL STUDENT AND GENERAL PRACTITIONER** By PAUL E. BOWERS, M.S., M.D. Octavo of 365 pages. Philadelphia and London, W. B. Saunders Company, 1924. Cloth, \$3.50

This book gives a very good presentation of the benign and malignant forms of mental disease. Although some of the descriptions are necessarily brief the descriptions are adequate for the purpose for which the book is intended.

To the reviewer it appears that the writer might have devoted more time to the modern psychological interpretation of not only the major forms of abnormal conduct but of the minor forms and it is felt that Freud's views in the interpretation of the neuroses might have been given a little more consideration. However, the book is well written and covers not only the various forms of the psychoses but also deals with mental deficiency, the neuroses and also gives a brief account of the Binet-Simon intelligence test. He also treats briefly the relationship of insanity to crime from which the student or general practitioner may learn what types are apt to be encountered.

Taken all in all it is felt that the book is well worth while for the purpose for which it is intended. S. R. LEAHY

**THE PRACTICAL MEDICINE SERIES** Eight volumes on the year's progress in Medicine and Surgery. Under the General Editorial Charge of CHARLES L. MRY, A.M., M.D. Series of 1924

**VOLUME I, GENERAL MEDICINE.** Edited by GEORGE H. WEAVER, M.D., LAWRASON BROWN, M.D., ROBERT B. PREPPE, A.M., M.D., BERTRAM W. SIPPY, M.D., RALPH C. BROWN, B.S., M.D.

**VOLUME II, GENERAL SURGERY** Edited by ALBERT J. OCHSNER, M.D.

**VOLUME III, THE EYE, EAR, NOSE AND THROAT** Edited by CASEY A. WOOD, M.D., CHARLES P. SMALL, M.D., ALBERT H. ANDREWS, GEORGE E. SHAMBAUGH, M.D. The Year Book Publishers, Chicago. Price \$3 per volume. Price of Series of eight volumes \$15

Volume I, General Medicine. This volume appears yearly is always worth while as it consists of abstracts of the best journals in the field. It is of value even to one who feels that he keeps well read as there are some articles that he will miss. It is a very handy book for quick reference.

The whole field of General Medicine is covered and the editors are particularly well qualified in their departments. After abstracting an article the practice is followed of commenting upon it favorably or not as seems proper to the editor. This is an interesting feature and increases the value of the book on account of the ability of the editors.

Volume II General Surgery. The year book upon general surgery is again presented in compact form and gives a very satisfactory review of the important advances during 1924.

The following features are stressed. In anaesthesia it is noted that ethylene is still being tried out, and observation seems to indicate relative safety but it is not devoid of danger. Many new instruments for special use have been described. The margin of safety in the surgery of diabetes has been widened by the use of Insulin.

Propaganda to furnish the laity with increased knowledge concerning cancer is bringing forth fruit. There is an increased tendency toward earlier diagnosis and treatment. Much attention has been given to the cause of cancer to experimental new growths, and to the post-operative treatment by radium and X-rays. It seems that blood transfusion has become more popular. Nerve injuries and the surgery of the sympathetic nervous system appear to have received an impetus. In the surgery of the thyroid more careful selection of cases for operation have been urged.

In the chest, the results of treatment of lung abscesses show improvement. Much interesting work and many good results are reported in the treatment of injuries to the heart and pericardium.

Abdominal surgery continues to hold its usual interest. Much attention has been given, especially to the stomach and duodenum. Abdominoscopy may open a valuable field. In surgery of the biliary tract Cholecystectomy continues the favorite procedure. The spleen has been frequently removed for splenomegaly.

Interest in fractures, stimulated by the late war, apparently shows no abatement. Improved methods of treatment are advocated. R. H. F.

Volume III The Eye, Ear, Nose and Throat. The size of this volume bears testimony to the many fine papers that have appeared during the year it covers in the subjects of the Eye, Ear, Nose and Throat. The completeness with which it reviews the recent work in these subjects makes it of the greatest practical value to the practitioner of medicine. For the specialist desiring a quick resume of the recent literature it forms a handy reference work. M. C. M.

## THERAPEUTIC VALUE OF OXYGEN IN PNEUMONIA \*

By C A L BINGER, M.D.,

(From the Hospital of the Rockefeller Institute for Medical Research, New York, N Y)

NEW YORK CITY

TO understand adequately the present status of oxygen therapy it is well to know something of the history of this subject. Shortly after the discovery of oxygen by Joseph Priestley in 1774 and the demonstration by Priestley and Lavoissier of its importance to respiration, oxygen very quickly invaded the field of therapeutics. Indeed it came to be hailed as a panacea. Here was the life-giving principle of the atmosphere without which animals could not live. It was natural to attribute to it great and varied curative powers, and we find it being used for a whole gamut of diseases from hysteria to bubonic plague, and in a variety of forms, even in the form of oxygenated bread in which the dough was raised with oxygen instead of carbon dioxide. The absurdity of this naive enthusiasm gradually became apparent. This period was soon replaced by one in which the therapeutic attributes of oxygen were denied and in which its use gradually fell into disrepute. The reasons for the change of heart are not far to seek. Experiments done in physiological laboratories showed that the blood normally contained its full load of oxygen, furthermore, that increasing the oxygen in the inspired air had no effect on metabolic rate, or, in other words, on oxygen consumption. It was reasonable, therefore, to doubt the efficacy of oxygen administration. But perhaps the chief cause for skepticism as to the therapeutic value of oxygen was to be found in the wholly inadequate methods in its administration which for many years prevailed. Who of us has not seen the familiar picture of a moribund patient with a "death rattle" in his throat, the hurried call for an oxygen cylinder and a funnel held over the dying man's face? And yet I venture to say that none of us has ever seen it benefit the patient or do more than bolster up temporarily the waning hopes of

his relatives. Someone has said that one might as well give tincture of digitalis by spraying it about the room with an atomizer as to give oxygen by the customary tube and funnel method. We know now that what is essential is to raise the partial pressure of oxygen in the patient's alveolar air to the point where it is great enough to restore the blood to as near its normal saturation as is possible. Recent investigations by Barach (1) and by Davies (2) have shown that the funnel method never and the nasal catheter method rarely can raise the alveolar oxygen tension to a sufficient level to accomplish the desired results.

Before discussing the essentials of a satisfactory method, let me remind you of the mechanism by which oxygen is transported in the body. Normal human blood contains about 15 grams of hemoglobin per 100 cc., this is sufficient to combine chemically with 20 cc. of oxygen. When the blood contains its full quota of oxygen, which is approximately 20 cc per 100 cc., we speak of it as being 100 per cent saturated. Now the blood in the arteries is almost completely saturated, containing instead of 20 volumes per cent, 18 or 19. It is therefore normally from 95 to 98 per cent saturated with oxygen. As it traverses the tissues it loses approximately 5 volumes per cent and the blood in the veins therefore contains about 13 volumes per cent. A slightly different method of expressing this is the following. The arterial blood which as we have said, contains approximately 19 volumes per cent, differs from the blood when completely saturated by 1 volume per cent, or, in other words, it is 1 volume per cent unsaturated, and the venous blood is 7. Assuming that the blood in the capillaries is a mean between arterial and venous blood in its oxygen content, the percentage unsaturation can be roughly expressed thus

(Continued on advertising page xiv)

perature and in the pulse rate, and sometimes, though not invariably, a reduction in the number of respirations per minute. A decrease in pulse rate is to be expected after oxygen administration, indeed this occurs in normal individuals. A reduction in the number of respirations does not occur so consistently. We believe there are other causes besides anoxemia in pneumonia which occasion rapid respiration. A more satisfactory understanding of what may be expected from the use of oxygen in pneumonia may be had from an analysis of a few cases treated in the oxygen chamber at the Hospital of The Rockefeller Institute. The most significant change, on inspecting the patient, is the change in color—the blueness of the lips and of the finger nails usually giving way to a normal pinkish color. There is frequently, though by no means invariably, marked improvement in the patient's psyche, with abatement, if not disappearance, of delirium, restlessness and drowsiness.

The charts of 5 cases treated in the oxygen chamber are included in this report. The upper section shows the average daily temperature, pulse and respiration. The next section shows the percentage unsaturation of the arterial blood taken while the patient was breathing atmospheres containing the per cents of oxygen indicated by the dots. The remainder of the chart is self-explanatory.

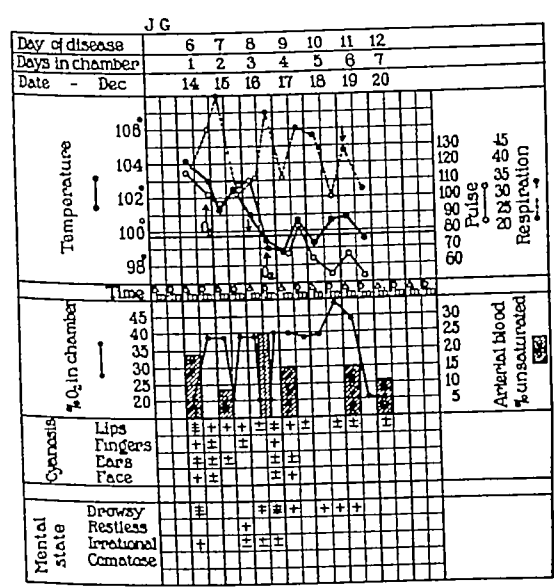

CHART I

Chart No 1 (J G) A case of Type II lobar pneumonia showed at the time of first arterial puncture while breathing atmospheric air a percentage unsaturation of arterial blood of 18. The patient was put into the oxygen chamber and the oxygen raised to 38 per

cent, with the result of a fall in his unsaturation to 7 per cent. Subsequently the patient was again exposed to atmospheric air, with the result that his blood became 25 per cent unsaturated. This condition again subsided after raising the oxygen in the chamber to 40 per cent. At this time there was a residual unsaturation of 15 per cent which did not yield to oxygen administration. This was probably due to the shunting of blood through consolidated un-aerated lung tissue to which the oxygen-rich atmosphere could not have access. The persistence of rapid respiration in spite of the gradual fall in pulse and temperature is consistent with both clinical and experimental observations which have been made, indicating that in pneumonia the rapid breathing is aggravated by anoxemia, though probably not primarily due to it.

CHART II

Chart No 2 (J S) An elderly man with Type IV pneumococcus infection showed a satisfactory response as far as disappearance of anoxemia was concerned, and this too is shown in Chart No 3 (S N), a case of Type I lobar pneumonia. That disappearance of anoxemia is, however, not necessarily associated with recovery is well shown in Chart 4 (S T) where there was a 28 per cent reduction in unsaturation with disappearance of cyanosis, but nevertheless the patient died. This patient had a severe blood infection which did not yield to antipneumococcus serum treatment.

Chart No 5 (W J) shows only a slight decrease in unsaturation, which was not very severe, 12 per cent, before oxygen therapy was started. This patient likewise died, with a septicemia of Type I pneumococcus, which persisted in spite of serum therapy.

$$C = \frac{1 + 7}{2} = 4$$

4 representing the volume percentage of unsaturation in the capillary blood. Lundsgaard and Van Slyke (3) have shown that clinical cyanosis appears when capillary unsaturation has reached an approximate level of 6 volumes per cent. This is true under normal circumstances when there is no marked anemia present. For the presence of anemia may mask the existence of a severe oxygen unsaturation, since the cyanotic color which indicates the existence of unsaturation depends for its appearance on the absolute concentration of reduced hemoglobin of capillary blood. This is an important point and it is well to remember that a patient with anemia may be suffering from oxygen want without the usual accompanying cyanosis. Clinically, cyanosis is certainly one of the outstanding features of oxygen want. We are now aware that oxygen want, even in a normal subject, may cause a trend of serious and distressing symptoms which may be acute in onset when the subject is suddenly exposed to atmospheres of low partial pressures of oxygen or when as in pathological states, there is something which prevents normal diffusion of atmospheric oxygen through alveolar epithelium. There are chronic forms of oxygen want with which we are not for the present concerned. In a disease like pneumonia we are dealing primarily with acute anoxemia. Within recent years the problem of oxygen transport in the body has received renewed attention largely at the hands of two British physiologists, Haldane and Barcroft, and their co-workers. Something in the nature of a controversy has sprung up between them as to whether, under conditions of oxygen want, the lungs have or have not the capacity for secreting oxygen. Without entering into this subject further let me mention it only in connection with a great number of experiments which have been done on normal individuals under conditions of oxygen deprivation, experiments done in negative pressure chambers, and observations made on various mountain peaks, from Teneriffe to Pike's Peak, and from Monte Rosa in Switzerland to Cerro de Pasco in the Peruvian Andes. A few years ago I had the privilege of taking part in an expedition to the Peruvian Andes, led by Mr. Barcroft for the purpose of investigating the effect of high altitudes on the human organism. If you will permit me, I will quote from a paper recently presented before the New York Academy of Medicine on this subject in which I have recounted some of the sensations of acute oxygen want and discussed its general significance.

"In the company of Dr. Alfred Redfield I left

Lima, which is at sea level, at about eight o'clock in the morning and within six hours we had crossed the continental water-shed at Ticlio at an altitude of some 15,000 feet. At this point a wash-out on the railroad necessitated our getting out of the train and walking approximately 200 yards to another train. I can best describe my own sensations by saying that I felt like an octogenarian who had spent a winter's night on a hard park bench and had been suddenly aroused by a hit on the head with a policeman's night stick. There was intense occipital and frontal headache, palpitation, precordial pain, rapid breathing, nausea, and a great sense of depression. The other members of the expedition experienced the same effects and the symptoms, including sleeplessness, visual disturbances, vertigo, and in some instances, elevation of temperature continued for several days. And yet all these symptoms were brought on in my own instance by a reduction of the percentage saturation of my arterial blood from 95 to 84. If we examine the dissociation curve of oxyhemoglobin which represents the manner in which hemoglobin combines with oxygen when subjected to increasing partial pressures of oxygen, we shall see that a change such as I have described was brought on by a fall in the tension of the alveolar air of approximately 50 mm. Now the object of all this is simply to show you what a profound series of untoward symptoms can be brought about by reducing the pressure of oxygen in the blood of a normal human being. And yet the great majority of patients with lobar pneumonia suffer from just such a reduction of oxygen pressure. Indeed we frequently see a percentage saturation very much lower than the one I have cited. Stadie showed, in a series of 33 pneumonia patients, that none recovered whose arterial saturation was below 70 per cent. If we consider that the patient with pneumonia has to fight a severe, progressing infection with its associated toxemia, it is perfectly clear that the added disadvantage of anoxemia may be such as to overcome him. And it becomes apparent that it is to his advantage to save him from the extra burden on his cardio-respiratory and central nervous systems which anoxemia involves."

That the oxygen content of the blood can be raised in patients suffering from pneumonia by the proper administration of oxygen has now been shown by several independent investigators. In Table 1 it will be seen that an increase in the percentage saturation of the arterial blood occurred in every instance after the patient had been exposed to an atmosphere containing about twice the concentration of oxygen present in ordinary air. In these patients one sees usually a slight drop in tem-

improvements have been made by Yandel Henderson (5) and Davies (2). Another satisfactory portable method is that of Barach (6) in which the patient breathes into a bag through a mouth piece or nose piece, provision being made for continuous removal of carbon dioxide. It is, to be sure, often very difficult in delirious patients to apply successfully a method requiring the use of either mask or mouth piece. To circumvent this difficulty a number of bed tents have been described, one by Leonard Hill (7), one by Roth (8) of the Battle Creek Sanatorium, and recently, one by Barach and Binger (9). These tents, though perhaps not practicable for general practitioners, have their place in hospital work. Of course, the ideal method of oxygen administration in hospital patients is the chamber of which several have been constructed. There are at present, to our knowledge, two such chambers used for therapeutic purposes, one at Guy's Hospital in London and the other at the Hospital of The Rockefeller Institute in New York. The one in New York (10) consists of an air-tight, fireproof room, 10 x 10 x 8 feet in dimensions, with a vestibule which allows passage in and out of the chamber with only slight loss of oxygen and a ventilation system to provide for cooling and drying the air and scrubbing it free from carbon dioxide. Two photographs of this chamber are shown here. The advantages of the chamber method are primarily that it permits of adequate and uninterrupted nursing care with the continuous administration of oxygen of known concentrations even to delirious and refractory patients. Furthermore, the chamber permits us to make physiological observations on the patient throughout the course of the disease.

It is our practice to take blood from an artery, usually the femoral, after the manner described by Fraser (11) before putting the patient into the chamber and then to raise

II Interior of chamber viewed through wide door on east wall. (a) window in south wall, (b and b') dampers of outflow ducts, (c and c') dampers of inflow ducts, (e) thermostat, (f) plug for electrocardiogram, (g) chain for bell signal, (h and h') automatic sprinkler heads.

the oxygen in the atmospheric air sufficiently to overcome the existing anoxemia. In our experience from 40 to 50 per cent will usually accomplish this, if indeed it can be accomplished. This fact is determined by a second arterial puncture. The chamber method has enabled us to put the use of oxygen on a quantitative basis. To obtain the best results with this as with any other drug it should be used quantitatively.

As indicated by the last two cases, when there is a persistent bacteremia there is little reason to expect recovery, even though the state of anoxemia has been successfully dealt with. This has been true in the main in most of the fatal cases, 16 of 21 fatal cases having had continuous bacteremia until death.

We are not in a position at this time to treat the subject of oxygen therapy in pneumonia

CHART V

statistically, as our series is not sufficiently large and the material is of too complicated a nature for statistical analyses. For the present we must confine ourselves to a clinical study of the individual patients for the proper evaluation of oxygen as a therapeutic agent. It is likewise unwise to expect too much of it. It is in no sense a specific. We believe, however, that it removes one of the obstacles which a sick patient must surmount on his road to recovery, and when it is properly given one may look usually for improvement in cyanosis, improvement in the patient's psyche, slight reduction in his pulse rate, and at times in his rate of respirations. This may be just sufficient to tide the patient over his critical days until he has established a sufficient immunity to handle his infection, often, to be sure, it may simply prolong his life by a few days when the bacterial infection is such as to overwhelm him.

A few words should be added as to what is meant by adequate methods of oxygen administration. There is at present no ideal method available for the general practitioner, but there are several methods which, in spite of certain disadvantages, accomplish the desired result. The desired result is to raise the oxygen of the inspired air to from 40 to 50 per cent, and to do this continuously with the minimum discomfort to the patient and a not too great extravagance in the use of oxygen. Methods which accomplish this are those described by J. S. Haldane (4) in which the patient breathes oxygen through a mask from a bag into which the gas is discharged at a known rate. Modifications of this method and it would seem,

CHART IV

the tissues along its course and furnishes a channel in which the ureter slides as it contracts arises from the cellular tissue of the base of the broad ligament, blends with and encloses the sheath of Waldeyer, formed of smooth muscle bundles, extending from the bladder. The sheath is thicker below the broad ligament. For this reason it is easier to palpate the ureter, anterior to the broad ligament.

### ANATOMY

The ureters are an inch apart in the trigone, about an inch behind the internal urethral opening, two inches behind the external urinary meatus on the anterior vaginal wall. They are about two inches apart at their entrance into the bladder, where they run through the bladder wall for three-quarters of an inch. These points are about one-half an inch in front of the lateral borders of the cervix, on the anterior vaginal wall about one inch from the crossing of the ureter by the uterine artery above the lateral fornix. After leaving the bladder, the ureters curve over the anterior vaginal wall and lateral fornix to a point half way between the lateral border of the cervix and the lateral pelvic wall where they are crossed by the uterine artery on a level with the internal os, about an inch from the lateral border of the cervix, about two inches from the ureteral opening in the bladder. From the point of crossing, the uterine artery accompanies the ureters for one to two inches, through the base of the broad ligament, to a point on the pelvic wall, just above the spine of the ischium where they turn upward on the pelvic wall, sometimes in front and sometimes behind the internal iliacs to the pelvic brim, where they leave the pelvis, through the infundicular pelvic ligaments mesial to the ovarian arteries. The right ureter is more often in front of the division of the common iliac, the left, behind.

*Technic of Palpation of the Female Pelvic Ureters Anterior to Broad Ligaments* See Picture No 1

To palpate the ureters from the ureteral orifices at the trigone, to the base of the broad ligaments. To orient their position. Imagine a line on the anterior and lateral vaginal wall, from a point about half an inch, in front of the lateral border of the cervix, where the ureter enters the bladder wall, to a point half way between the lateral border of the cervix and the lateral pelvic wall. Here the ureter passes under the base of the broad ligament. The fingers introduced into the antero-lateral vault of the vagina, counter pressure is made downward, through the abdominal wall, to the side of the symphysis pubis with the abdominal hand. Draw the fingers forward. As the tissues slip through the fingers, the ureter is felt as a cord like body about the size of a goose quill, displaced in its bed of cellular tissue,

No 1 Technique of palpation anterior to broad ligaments Described by author

as it slips through the fingers. It can be felt again and again, and rolled from side to side under the palpating fingers, by moving the fingers towards the broad ligament and drawing them forward toward the bladder. The normal ureter is not tender. If diseased it is thickened, enlarged and tender, sometimes as large as a lead pencil or larger. Palpation brings an intense desire to urinate. It is easy to distinguish a diseased ureter by comparing it with its fellow, as it is rarely diseased to an equal extent.

*Technic Posterior to Broad Ligament* See Picture No 2

A Judd, *Journal of Obstet*, Vol lxxiii, No 6, 1910, advises palpating it posterior to the broad ligament, where it is felt above the spine of the ischium sometimes as high as an inch above. He advises palpating it with the fingers in the lateral vaginal fornix, behind the broad ligament. Sweeping the fingers above the point of its location and then slightly bending the ends of the

## THE IMPORTANCE AND TECHNIQUE OF PALPATION OF THE FEMALE PELVIC URETERS\*

By DAVID W TOVEY, M D,

NEW YORK CITY

Howard Kelly, in the *Annals of Surgery*, 1906, wrote "I am glad to have this opportunity of calling your attention to an important but still much neglected diagnostic point. As the normal ureters are to be found so easily, it is yet more easy to detect and examine diseased ureters. In a number of instances in which the diagnosis had not been made, he was able to set the question entirely at rest, as rapidly as he could carry the finger into the vagina, sweeping it over the anterior vaginal wall. One side would be normal, while on the other, a thick hard ureter. He says 'I cannot say too much in extolling a method of diagnosis so simple and certain as this'."

Max Sanger in the *Archive of Gyn*, Vol I, 1886, in an article, "Palpation of the Ureters in the Female" remarks that it was peculiar that he had not before included palpation of the ureters, in his vaginal findings. He reports cases of ureteritis, treated for long periods, for cystitis.

Albert Judd, *Journal Obstet*, vol lxxxiii, No 6, 1916, describes a method of palpation of the ureters behind the broad ligament. He claims that they could be felt in 90 per cent of the cases during routine vaginal examination. In an article read before the *American Association Obstet Gyn*, 1920, I said "Palpation of the pelvic ureters should be a part of every vaginal examination, and described the technic of palpation of the ureter, anterior to the broad ligament."

Again in 1923 in a paper read before the same association. The Importance of Palpation of the Pelvic Ureters in the Diagnosis of Abdominal Disease, I said "The anastomosis of the nerve plexuses of the ureter, with the nerve plexuses of all the abdominal nerve plexuses, explains why pain due to disease of the urinary tract may be intensified in different regions of the body, and why diseases of the ureter and kidney are mistaken, for different abdominal conditions,

from cervicitis and ectopic pregnancy to gall stones and gastric ulcer! Palpation of the ureter will give the clue to the diagnosis."

Mayo reports most of the cases of kidney and ureteral stones which they encountered, had been mistaken for abdominal conditions and operated on for diseases of the ovary, stomach, gall bladder or appendix.

Barney reports That 18 per cent of his cases of ureteral calculi, had one or more previous operations. The urine was negative in 8 per cent and the X-ray in 6 to 11 per cent of the cases.

Knestschnier reports that in 44 per cent of his pyelitis cases, were operated on for mistaken abdominal conditions.

In a former article I expressed the belief That many of the symptoms of the cystitis following gynecological operations, are due to ureteritis, as the cystoscope shows a normal bladder. That infections of the cervix, are a frequent cause to ureteritis, giving symptoms of cystitis and reflex pains in different parts of the abdomen. 15 per cent of gynecological cases have diseases of the urinary tract, according to Danasseuther. A thickened ureter will give a clue to the diagnosis if the technique to be described is followed.

The normal ureters can be palpated in most cases. There is nothing between the finger and the ureter but the vaginal wall. It is easier to palpate the ureters than the ovaries, as the ureters under normal conditions are always found in the same position in the pelvis. Moderate displacement of the uterus in any directions alters but slightly the relation of the ureters to each other or to the sides of the pelvis. The cervix if nearer to one side of the pelvis, is nearer to that ureter than to the other, but the position of the ureters in their course through the pelvis is not changed. The ureteral sheath described by Sampson, *Johns Hopkins Bulletin*, Feb, 1904, is formed by the peristasis of the ureter, from

In the following cases palpation of the ureters gave a clue to the diagnosis

1 U S 25 years

Nausea, pain epigastric distress, temp/104 pain and tenderness in the region of the appendix. Appendectomy advised by her physician Vaginal examination Right ureter enlarged, tender palpation brought an intense desire to urinate. The left ureter enlarged and tender but not as large or tender as the right A diagnosis of pyelitis was confirmed by examination

2 N H 32

Pain felt over left ovarian region, worse at menses No bladder symptoms Sent for operation of removal of ovary Left ovary normal. Left ureter enlarged, tender Palpation brought intense desire to urinate Diagnosis of ureteritis Examination by cystoscope and ureteropyelogram, showed stricture of the lower ureter

3 S U 30 years

Sent with diagnosis of ectopic pregnancy of an acute gall bladder Complained of an acute pain and tenderness in the gall bladder region with chills and fever, nausea and vomiting A half grain of morphine gave no relief Vaginal examination Right ureter enlarged, tender and small stone felt about one inch above the bladder Diagnosis confirmed by cystoscope and ureteropyelogram Patient later passed a stone about the size of a shoe button

4 H K 48 years

Tumor right side of abdomen diagnoses as enlarged gall bladder Frequent urination. Blood in urine attributed to inflamed urethral meatus X-ray negative Vaginal examination right ureter enlarged and tender, palpation brought intense desire to urinate Pyelogram Pus kidney with large soft stone size of a plum in kidney pelvis Large pyonephritic kidney and soft stone removed at operation

5 Y D

Sent with diagnosis of ectopic pregnancy Last menses three months ago Severe pain in right ovarian region accompanied by spotting Urine examination normal Vaginal examination Uterus enlarged size 2½ months, Ladnib

sign of pregnancy present. Right ureter enlarged, tender, intense desire to urinate on palpation. Diagnosis of pregnancy with ureteritis and pyelitis. The spotting was due to reflex disturbance following ureteritis

6 S H 29 years

Sent for operation of ectopic pregnancy. Last menses two and one-half months. Irregular bleeding, attacks severe pain in right ovarian region, nausea and fainting. Patient said pain felt as if a tube the size of a banana was in the pelvis. Examination. Uterus enlarged, softened, Ladins sign of pregnancy present. In the left corner a hard mass the size of a plum. Bloody discharge of brownish color from vagina. Right ureter enlarged and very tender. Palpation brought an intense desire to urinate. Diagnosis. Pregnancy two and one-half months in left corner. Ureteritis due to stone, confirmed by cystoscopic examination.

7 D S 60 years

Large kidney shaped mass on the left side extending into kidney region. Palpation revealed normal ureter. Ureteropyelogram showed normal ureter and kidney pelvis. Diagnosis. Tumor not kidney, sarcoma of spleen removed at operation.

8 J U 35 years

Since birth of child three years ago indigestion,

pain right abdomen, frequent urination. Treated for cystitis advised to have appendix and right ovary removed. Her physician thought he felt an enlarged appendix. Vaginal examination. Cervix lacerated, eroded and infected. Pelvic organs normal. Right ureter enlarged and tender. Palpation caused an intense desire to urinate. Diagnosis. Cervicitis and ureteritis. Amputation of the cervix and local treatment cured the patient. Physician felt thickened ureter.

9 M P 35 years

Patient sent by her physician who thought he felt an enlarged appendix. Complained of attack of severe pain. Right iliac region, nausea, epigastric distress, frequent painful urination. Vaginal examination. Right ureter enlarged, size of a finger, very tender. Palpation brought an intense desire to urinate. Thickened ureter felt abdominal palpation and thought to be an enlarged appendix. Diagnosis. T. B. Kidney confirmed by cystoscopic examination.

10 J R 25 years

Pain on the right side. Indigestion, constipation, epigastric distress. Operation for appendectomy. Right corphorectom and Lane kink without relief. X-ray and urine negative. Palpation hard tender mass in right lower ureter. Diagnosis. Stone in ureter confirmed by examination.

## DIAGNOSTIC CURETTAGE IN SO-CALLED IDIOPATHIC UTERINE BLEEDING\*

By EMIL NOVAK, M.D.,

From the Gynecological Department of Johns Hopkins Medical School

BALTIMORE MD

**N**O subject in gynecology has been more extensively studied and written about than that of uterine hemorrhage. There are of course certain cases in which the mechanism is rather obvious, i. e., those in which it is caused by ulcerative and destructive processes, such as cancer. With these we shall not concern ourselves in this paper. Nor shall we discuss that large group in which a pelvic lesion of some sort is present (chronic adnexitis, ovarian or uterine tumor, displacement, etc.), although there is much uncertainty as to just how the bleeding is brought about. The type of bleeding with which we shall deal in this paper is that which is noted in the en-

tire absence of any tangible anatomic lesion of the pelvic organs.

Such bleeding has been variously designated as "idiopathic," "essential," or "functional." It may occur at any period of reproductive life, but is most frequent at or near the menopausal age. It may be observed in young girls at or near the age of puberty. In some cases, perhaps most characteristically, it takes the form of menorrhagia, while in others metrorrhagia is observed. It is not within the scope of my paper to discuss the clinical aspect of this subject, except perhaps to stress again the fact that such bleeding, perhaps of extreme degree, may occur in patients whose organs, so far as the most careful bimanual examination will reveal, are perfectly normal.

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 12 1925.

Many explanations have been offered for this form of menstrual abnormality. The pathological study of the subject may be said to date from the work of Scanzoni in 1863. The explanation offered by this author was a purely anatomical one, the bleeding being attributed to a chronic inflammation of the myometrium. It is of interest to note that the rôle of the myometrium has been reemphasized by certain much more modern investigations. Under this head may be put the theory of Theilhaber, that the bleeding is due to an "Insufficiencia uteri" brought about by a replacement of muscle by connective tissue, and also that of Anspach, who believes it may be explained by abnormalities in the distribution of the elastic tissue about the blood-vessels.

In this connection, one may also mention the view urged by Pankow, Rees, Findley, and others that arterio-sclerosis of the uterine vessels plays an important part in the causation of such bleeding. It is probable that such factors as these play a part in some cases. For example, one will at times observe, after either a miscarriage or a full-term delivery, the most persistent bleeding, which continues after even the most thorough curettage. Bleeding of this type is especially frequent, in my experience, in women who have had many pregnancies in rather rapid succession. The only explanation which seems possible is that there is a deficiency in the uterine musculature, although microscopic demonstration of such a deficiency is not nearly so satisfactory as might be wished.

The same statement may be made as to the occasional role of arterial disease in the production of uterine bleeding. From time to time one sees patients at or near the menopause, and not infrequently far beyond the menopause, who exhibit a troublesome, though usually very moderate, metrorrhagia. The blood pressure in such cases is commonly quite high, and other symptoms of hypertension are usually present. Diagnostic curettage is, of course, indicated, because of the ever-present danger of malignancy. Not infrequently, however, the curetting will yield only a very scant amount of tissue, which under the microscope is found to be a normal, usually senile endometrium. Such a syndrome is sufficiently frequent to make us feel that arterial disease may in at least a small proportion of cases play a part in the production of uterine bleeding.

Speaking generally, however, uterine bleeding of either of the two types just described is not included under the designation of essential, idiopathic or functional bleeding. The latter occurs in women who otherwise are apparently in good health, and in whom the bleeding can not be explained by such factors as repeated

pregnancies, myometrial deficiency, or arterial disease. For diagnostic, even more than for therapeutic, purposes curettage is clearly indicated whenever such unexplained bleeding has persisted for any length of time. When the bleeding occurs in a woman at or near the menopausal stage, the vital importance of such a procedure is obvious. In a large proportion of cases the microscopic examination of the scrapings will reveal a perfectly characteristic picture, which we have therefore come to associate with this form of bleeding.

The condition is spoken of as hyperplasia of the endometrium. It was described originally by Cullen, as far back as 1900, and in recent years has been the subject of much study, especially in the German clinics and laboratories. At the last meeting of the American Gynecological Society (1924) Martzloff and I presented a detailed study of 66 cases which had been encountered in our laboratory of Gynecological Pathology at the Johns Hopkins Hospital, in less than five years. The lesion is therefore a relatively frequent one.

The term hyperplasia is an appropriate one, because there is evidently a genuine increase in the tissue elements of the endometrium, both epithelial and stromal. The hyperplasia of the epithelium elements is indicated by the thickening of the surface and gland epithelium, so that, especially in the latter, it is not uncommon to find more than one layer of cells, with rather heavily staining nuclei. The stromal increase is indicated by the frequent presence of considerable numbers of mitoses, though this finding is not constant. At times the stromal overabundance is so marked that large fields of stroma are noted, the gland elements being relatively sparse. In other cases, the reverse is observed.

From a diagnostic standpoint, however, by far the most characteristic feature is the gland pattern. Large cystic glands are found, often side by side with glands which are narrow and undilated. There is thus produced what we have called a swiss-cheese pattern. In marked cases this is extremely well-defined, so that the diagnosis can be made at a glance. In the milder cases, the characteristic picture may be seen only here and there in the section, and even then may not be at all outspoken. Speaking generally, however, it may be said that the microscopic diagnosis is extremely easy. For a detailed description of the pathology of this interesting endometrial lesion, as well as of its clinical aspects, the reader is referred to the above quoted paper by Novak and Martzloff.

The gross picture in the endometrium in cases of hyperplasia differs in different cases. In the most typical instances, there

is an enormous overgrowth, usually polypoid, producing the picture which has so commonly been spoken of as polypoid endometritis. The latter term is a misnomer, because of the usual absence of any inflammatory changes in the endometrium. True endometritis has little tendency to cause polypoid overgrowth. Where the endometrium is so overabundant the curette will bring away great quantities of polypoid tissue, so that the suspicion of malignancy may be strong. The distinction, however, is usually very easy to make even at operation. No matter how abundant and polypoid the endometrium may be in hyperplasia, its surface is usually smooth and intact with no evidence of the friability and breaking down seen in all except the most incipient cancers. Especially startling are the cases of hyperplasia in young girls, where the curette may at times bring away huge quantities of the hyperplastic endometrium. In a larger number of cases, however, only a moderate overgrowth may be observed, while in still others there may be little or no gross evidence of the lesion. And yet the microscopic picture is the same regardless of the degree of gross overgrowth.

Since the endometrium in functional bleeding so commonly shows hyperplasia, the question arises as to whether the bleeding may not be due to the endometrial lesion. If this were so, it could scarcely be called functional, in the narrower sense of that much abused word. There is much evidence, however, to show that the endometrial condition, and the bleeding, instead of being associated as cause and effect, are alike due to a more fundamental cause, a disturbance of ovarian function. For example, hyperplasia of the endometrium is, generally speaking, found only during the years of active cyclical ovarian function. Abolition of the latter by such means as X-ray, radium, or castration will inevitably be followed by cessation of the bleeding. On the other hand mere removal of the hyperplastic endometrium by curetting is followed in a large proportion of cases by a recurrence of the hyperplasia and also of the bleeding. In other words the underlying cause, i.e., the functional disorder of the ovary continues to exert its effects. Just what the disorder is it is impossible to say in the present state of our knowledge but certainly it seems fair to assume that it is in the nature of a hypersecretion of the ovary or one of its constituent elements. This question, as well as that of the associated histologic changes in the ovary, has been more fully discussed in a recent paper by the present author.

So common is it to find hyperplasia in cases where there is no demonstrable gross disease in the pelvis that failure to do so should lead to the suspicion that some of the better recog-

nized causes of bleeding, perhaps a submucous myoma or an unsuspected chronic adnexitis, may have been overlooked. On the other hand, in a certain proportion of cases without demonstrable gross disease the diagnostic curette will bring away tissue which is, so far as we can determine, perfectly normal. We thus apparently have two groups of functional cases, one in which the endometrium is normal and a second, much larger group, in which the typical picture of hyperplasia is found. Just what makes the difference between the two groups we cannot say, although it is a temptation to believe that they are produced by different types of functional aberration. This question is now being studied in our laboratory.

Certainly there is nothing incredible in the concept that ovarian disorders may cause alterations in the endometrium. No stronger proof of this is necessary than that offered by the striking changes in the histology of the endometrium at different phases of the menstrual cycle, changes which are universally conceded to be due to cyclical function of the ovary. Why, then, could not an abnormally functioning ovary bring about an abnormal change in the ovary? As far back as 1882 Brennecke spoke of what he called "endometritis ovarialis," an endometrial lesion due to ovarian disorder. It was probably the condition now designated hyperplasia. Even before this, in 1875, Olshausen had described, as a cause of severe and long-continued hemorrhage, the lesion which he designated "endometritis fungosa." His description leaves little doubt that it was identical with what we now more properly call hyperplasia. Olshausen looked upon the condition as a chronic inflammatory process, and unlike Brennecke, did not in any way associate it with disturbance of ovarian function.

A final emphasis may be placed upon the importance of hyperplasia in connection with bleeding at or near middle life, i.e. during the cancer epoch. At least one-half of all cases are seen at or near the menopause. We have, very properly, been urging upon women the importance of bleeding as a danger signal of cancer during these years. The external forms of cancer, especially squamous cell cancer of the cervix, are ordinarily easily diagnosed by inspection and palpation, with confirmatory microscopic examination of cervical clippings if necessary. The internal forms, i.e., adenocarcinoma, are diagnosable only by means of microscopic examination of scrapings. The point that I wish to emphasize is that, in cases of menopausal bleeding where diagnostic curettage is necessary, the microscopic examination of the scrapings will show the perfectly benign condition of hyperplasia considerably

more often than adenocarcinoma. This is all the more true if we are dealing with patients still in the menstruating epoch, for adenocarcinoma, in a large proportion of cases, is noted in women well beyond the menopause, while hyperplasia is characteristically confined to the menstruating years. There can be no harm in presenting this hopeful aspect of the matter to patients in whom we are faced with the possibility of cancer. I believe that women will be all the more willing to submit to diagnostic curettage, when this is indicated, if we tell them, as we truthfully can, that in a large proportion of cases, even where no gross benign lesion like inflammatory disease or a

hobnail is present, the cause of the bleeding will be found to be a condition which not only is non-cancerous, but which does not even exert any predisposing influence in the development of cancer.

### IDIOPATHIC UTERINE BLEEDING FROM THE CLINICAL STANDPOINT\*

By WILLIAM P. HEALY, M.D., F.A.C.S.,

NEW YORK CITY

UTERINE bleeding must always be regarded as a symptom indicative of either physiologic or pathologic activity.

This activity may be local in character and may originate in the endometrium, the uterus and adnexae or the adjoining pelvic structures. It may on the other hand result from constitutional disturbances or from endocrine imbalance.

It may be of a physical or indeed even of a psychic character. For the rhythmic recurrence of the menstrual cycle in some women seems to be so delicately balanced that it is easily disarranged by many of the ordinary activities and responsibilities of life.

This discussion is to be restricted to the type of uterine bleeding known as idiopathic, but often discussed under other headings such as myopathic essential uterine insufficiency, etc.

The title of the paper indicates that in this group we are unable to find any gross pathologic change occurring uniformly in all of the cases to account for the bleeding.

The microscopic study of the endometrium is usually reported as showing a condition of chronic hyperplastic glandular endometritis. Often indeed it is reported as showing normal endometrium with no pathologic change. Under what clinical conditions then do we find this symptom complex?

It may occur at any age from puberty to the menopause but is, on the whole, probably more common in the first half of menstrual life, that is before the 30th year. George M. Brown,<sup>†</sup> in a study of 2,447 cases of menstruation reports that 72.3 per cent were regular in type from the beginning, 18.9 per cent became regular in

a certain time and only 8.7 per cent remained irregular or abnormal.

As far as I have been able to determine idiopathic uterine bleeding occurs just as frequently in the physically well developed as in those poorly nourished and I have been unable to find that there was any underlying neurasthenic or psychic factor common to the group.

It occurs in married and single women but is more apt to be associated with sterility than otherwise.

There is a natural division of the cases into two groups, those which occur at puberty and those occurring at the climacteric.

In each group one can readily understand that there may be an endocrine imbalance for they are placed at times which represent epochs in the life cycle of the female. Moreover one must realize that the anatomic features present while possibly normal for each group are totally different in the two groups. At puberty we have immature structures about to take over new function, whereas at the climacteric we are dealing with tissues which have functioned more or less rhythmically for many years and which may have experienced extensive changes in their histologic structure as a result of pregnancy.

The chief and practically the only primary symptom is abnormal uterine bleeding indicated by a profuse or prolonged menstrual flow, which may be continuous or intermittent, recurring after intervals of a day or two. Altogether the patient may bleed on more days of the month than she remains free from bleeding.

There are other symptoms but practically all of them result from the secondary anemia which follows the persistent bleeding.

Examination of the patient's blood has not given us any information of practical value from

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 12, 1925.

† Brown G. M. *Jour Mich State Med Soc* Jan., 1924.

either the diagnostic or the therapeutic standpoint

In the years before the advent of gland therapy the tendency was to treat instances of abnormal uterine bleeding of this type, which did not respond to ordinary medical treatment, by curettage of the uterus. This procedure often was successful and when it failed, curettage was repeated from time to time as the bleeding recurred. Finally in many instances hysterectomy was done in order to bring about permanent cure.

Since the advent of organotherapy persistent attempts have been made, with more or less success, to control the bleeding by means of oral or hypodermic administration of various gland substances or extracts, either singly or in combination of several glands. In general it must be admitted that the results of such treatment have not been satisfactory in either the adolescent or the climacteric groups. From time to time individual cases seem to respond to one preparation or another or to one combination or another of the gland substances.

In the writer's experience, however, it has been quite impossible to proceed with any degree of assurance as to ultimate results with this form of therapy.

Nevertheless we continue in the use of the various preparations more or less empirically for as we have said there undoubtedly is every reason for believing an endocrine imbalance exists in many of the cases of idiopathic uterine bleeding.

In the younger group of cases I would suggest that the treatment at first should be along general medical and hygienic lines, if the results are not satisfactory after a reasonable time, then organotherapy should be resorted to. In the event of failure of this plan, the next procedure should be curettage, which should not be too vigorous and should not be repeated in less than four to six months in these younger women.

If the first or second curettage fails to give relief from the bleeding, one can then fall back upon the use of radium applied within the uterine cavity above the internal os. This in my experience is a safe form of therapy in the girl or young woman, provided the dose is properly controlled and it will nearly always give a good result. It is much better I believe, never to use radium in a young woman without having at hand a report on the microscopic study of the tissue removed by curettage.

This is essential for if the interglandular stroma is made up of a structure closely resembling lymphoid tissue it will be very susceptible to irradiation and will melt away very quickly and cause a complete disappearance of the endometrium.

This naturally would result in a more or less

permanent amenorrhoea, a very unfortunate circumstance in a young woman. With regard to dosage it would seem safe to use from 150 to 300 milligram hours, depending somewhat upon the age of the patient and the size and consistence of the uterus. The smaller dose is indicated in the young girl and in the small uterus. If this fails to give the desired result it should positively not be repeated in less than six months.

The small dose is naturally slow in bringing about changes in the histologic structure of the tissues irradiated and it may be several months before these changes are of sufficient magnitude to influence the symptoms. A second dose of radium applied during this time will undoubtedly cause cumulative radiation effects in the tissues and may result in amenorrhoea for a long time, if not permanently.

We have carried out the plan of treatment outlined for the younger group of cases for the past ten years, in other words since radium has been available. On the whole the results have been reasonably satisfactory in the control of the bleeding, the maintenance of a normal menstrual cycle thereafter, and the occurrence of conception resulting in the birth of normal children.

So much for the younger group. What shall we do for the older women, forty years of age or older, who present no gross pathology but in whom idiopathic uterine bleeding occurs?

Our problem here is much more simple, it is seldom necessary to consider the question of future pregnancy or even retaining the menstrual function. If these issues are paramount the patient should be treated somewhat along the plan outlined for the first group. If not we need only rule out the question of malignancy by a thorough curettage with microscopic study of the removed tissue and at the time of the operation insert radium capsules into the uterine cavity above the internal os for a total dosage of 800 to 1,200 milligram hours. This dosage seldom fails to stop the bleeding within two to six weeks and usually results in permanent amenorrhoea especially if 1,000 or more m g hours treatment is given.

Therefore it may be said that this is practically a specific remedy or method of treatment in this group of cases.

In the literature one finds references to many other forms of treatment for idiopathic uterine bleeding such as irradiation of the thyroid gland, or the spleen, or the liver with the roentgen ray, with reports of cases successfully treated. Also the intravenous use of sera of various kinds and of solutions of sodium citrate intravenously. The writer has had no experience with any of these methods.

## TREATMENT OF FRACTURES OF THE NECK OF THE FEMUR\*

By WILLIAM CRAWFORD WHITE, M.D., F.A.C.S.

NEW YORK CITY

A SURVEY of recent literature does not give one any firm belief in any method. We had made use of the Whitman method at the Lincoln Hospital but I did not feel sure that it was the only method of treatment. In 1890 the abduction method was introduced but it has not yet had a universal acceptance.

Royal Whitman<sup>1</sup> states that "in aged subjects it has been demonstrated that efficient treatment of the fracture by the abduction method is actually more conservative than life-saving neglect, since it relieves pain, and permitting elevation of the head of the bed and frequent changes of posture, prevents hypostatic congestion and bed sores. Furthermore it has long since been proved that neither advanced age, or the situation of the fracture precludes repair if the opportunity is assured. Shortening of the limb and lameness are not inevitable. The spica is retained for eight to twelve weeks or until it may be assumed or demonstrated by Roentgen-ray examination that union is sufficiently firm to permit movements of the limb. On its removal the patient should remain in bed several weeks for muscular reeducation and the restoration of function in the disused joint, the limb being drawn out to the limit of abduction by the attendant. Full weight bearing is not permitted until free and painless movement and Roentgen-ray examination indicates stability of repair. Rarely less than six months and in the central type it may require a much longer time. If, therefore, an early locomotion is desired a protective hip brace should be provided. In others there appears to be a preliminary so-called absorption of part of the neck, but in most instances the fragments eventually unite if contact is maintained for a sufficient time." "Since if properly applied, the abduction method assures fixation of the fragments, the insertion of nails or screws is unnecessary and even harmful because of injury to cancellous structure on which repair depends and if, as in some instances, there was subsequent absorption of the central part of the neck, the fragments would be actually held apart rather than opposed. A bone peg may in some instances promote union, but functional results are often far from satisfactory, and indications are insignificant in number."

There does not seem to be any question about bone union in the fractures about the base of the neck, but when we come to the central fractures we have different reports. Johan Waldenstrom of Falun, Sweden<sup>2</sup> had 14

cases treated with the abduction method, and had union in eight, three pseudo-arthroses with good function and three pseudo-arthroses with bad function. Delbet and Basset<sup>3</sup> have never seen union of an intracapsular fracture except in cases fixed by metal screws. Uno Lindberg of Upsala, Sweden<sup>4</sup>, had five cases of transcervical fracture with union in three, and he quotes O. Lofberg<sup>5</sup> who has had 70 cases with union in 39 cases when treated by the abduction method. Of 98 cases 63 had presented an excellent or a good functional result.

Campbell<sup>6</sup> had 28 central fractures treated by the abduction method and 85 per cent gave a good functional result, by which is meant that the patient was able to walk without support, pain or discomfort, and with every evidence of bony union. A slight limp persisted in the majority, though quite a number walked perfectly. In two studied a gradual coxa vara developed, although union had appeared firm. He believes that there is no method by which we can determine union except time, with the development of perfect function and stability. A. O. Wilinsky<sup>7</sup> reports two cases treated by fixation with a bone peg, in an abduction spica. He expresses doubt if more than 15 per cent of intracapsular cases obtain union with the abduction treatment in those insufficiently or badly treated. He expresses no opinion about those well treated. He says "that if tried the abduction treatment requires at least four months" and then if no union "an operation at this late date would be futile because of changes, whereas if it is done early there would be a closer approach to the normal." He advises in the robust a living graft of bone through the trochanter into the head. Then abduction in a plaster splint for two months. At the end of three months allow ambulatory treatment with braces until six months, when they may be discarded.

Again Campbell<sup>8</sup> says that "if no union occurs in a central fracture of the neck of the femur at the end of eight weeks, in all probability an ununited fracture exists. Clinical experience teaches us that under the most favorable circumstances union is delayed in this region, and as stated a permanent status of non-union is reached much earlier."

We have then as choice of treatment, the palliative, the traction and suspension with adhesive or caliper traction, the closed reduction with the abduction and plaster spica, the bone graft, and the reconstruction operation of Whitman. The palliative method is chosen only when the patient is so decrepit and asthenic that any interference would be judged

\* Read before the Surgical Section New York Academy of Medicine

impossible. This is largely a matter of personal opinion and will vary with different surgeons as to the percentage. I believe that this group should be small. The most of the patients obtain the best results with the plaster spica after closed reduction and complete abduction. This may be qualified by saying that suspension and traction has gained some friends who use it in the treatment of some fractures about the base of the neck, I have not had sufficient personal experience of the traction to express an opinion. The reconstruction and the bone peg operations should be reserved for the occasion when union can not be obtained.

It is my experience that the plaster spica with its encasement of the patient is in some patients a severe mental and physical strain, and that it can not be used in all cases. To obtain a satisfactory reduction and application of the abduction method a general anaesthetic is required, and in some this is a dangerous procedure. Our abduction method tried to follow the method of Dr. Royal Whitman. We break up the fracture site and do not allow a Roentgen-ray diagnosis of impaction to keep us from attempting to improve the position. We think that this is important in order to obtain sufficient abduction and internal rotation. We use the Hawley table and apply a plaster spica from toes to axilla with the extremity in abduction, extension and inward rotation when possible. This last point is sometimes difficult for us to obtain. To our annoyance at the end of the operation we sometimes find that we have not as much inward rotation as we had thought. The other lower extremity is left free and a window is made in the abdominal wall for meal expansion or else a dinner pad is inserted. After the first day it is our custom to turn the patient on his face twice a day. The elevation of the head of the bed helps prevent pulmonary congestion. A big help to the patient is any overhead apparatus that makes it possible for the patient to help himself a little. I do not like the method in which the both lower extremities are kept in abduction in plaster in order to fix the plaster. It is uncomfortable and almost makes it impossible to turn the patient over on his face.

The spica is kept on from 60 to 90 days with the longer period for the intracapsular fractures. There is but little if any advantage in removing the foot and leg portions of the cast before the whole comes off, and there is the disadvantage that there is often much pain and discomfort, with edema. After the cast has been removed the patient is kept in bed for several weeks more, and then he is allowed crutches and home, with instruction not to bear weight within six months of the time of

the accident. A supportive splint is desirable but not usually possible. Massage is of great help. We find that the knee often gives them trouble over a long period, and I wonder if the full extension and the forcetful internal rotation does not cause too much strain on the ligaments with a secondary peri-arthritis.

I feel that in the large majority of cases the abduction treatment of Whitman is indicated and that it may be successfully used in both the intracapsular and extracapsular fractures. In central fractures one may obtain bone union and good function. However there are central fractures in which bone union does not occur and one must be prepared for additional treatment. It seems to me that a wait of one year to see if bone union will occur is too conservative. On the other hand immediate operation is too radical. I prefer to believe that, in many of these non-union cases, it can usually be determined at the end of two months that there will be no union. Then one has the choice of the bone peg or the reconstruction operation.

I have had no personal experience with the bone graft in the fracture of the neck except to watch several well known surgeons struggle with it and make me realize that it is a difficult procedure. I have had two reconstruction operations to report and will show lantern slides tonight of one. The operation is easier than the bone graft. However I believe that the bone graft operation is to be preferred to the reconstruction in the cases operated upon under one year.

The facts given below are based on a review of forty cases—thirty-six from the wards of the Lincoln Hospital and four private cases. Of the forty cases, nine had no active treatment and thirty-one had the abduction treatment of Whitman. Two of these abduction cases later had the reconstruction operation of Whitman.

One of the palliative cases had a fracture of the neck of the femur in a femur stump that had been non-weight bearing and so had no indication for interference. Of the other eight cases one died in the hospital, two months after admission and five were transferred.

Of the thirty-one cases treated by the abduction treatment, four died in 25, 22, 42 and 5 days respectively after the application of the plaster. And they were of the ages 69, 60, 58 and 56 years. One had pulmonary tuberculosis, one developed lobar pneumonia, and two gradually became irrational, incontinent and died.

I have made late examination on three of the palliative cases and nineteen of the abduction cases, with an inspection of the early and recent Roentgen ray films of nineteen. Fourteen of the cases were intracapsular and I have traced ten, twenty-six were extracapsular and I have traced twelve. Of the intracapsular cases, five show clinical evidence of union at the fracture site.

and I believe that there is bone union. Of the non-union cases two go about with canes and have only slight pain. They have had increased shortening since leaving the hospital. Two had considerable atrophy of bone with marked pain in the hip and disability and came to the reconstruction operation of Whitman. Both gave good results. The last is only seven months since the abduction treatment. There seems to be fibrous union only. She walks in a splint with crutches.

All the cases had some shortening varying from one-half to two inches in one case of non-union. Eleven required the use of a cane and eleven walked without support and had only a very slight limp. The usual abduction was from thirty to forty-five degrees. Of the abduction cases four later failed to have abduction. Three of these were non-union cases while the fourth was an excess callus case. Of the three cases that were followed that had no active treatment one was paralyzed, one had no abduction and the other had thirty degrees. This last case was a fracture with no displacement. The abduction cases had good rotation with the exception of the cases without bone union and one that was improperly treated at the start. One of the palliative cases had good rotation and the other was only fair. Flexion of the thigh with the leg in extension was absent in the non-union cases but present in the others.

The case with the excess callus was bed ridden. The housewives usually were able to do one-half

to three-quarters of their work. The men were not able to do more than a light job.

### SUMMARY

1 Eleven out of the twenty-two cases could walk without a cane, pain or discomfort and gave clinical signs of union.

2 Five out of the ten intracapsular fractures appear to have bone union. All the extracapsular fractures had bone union.

3 We had shortening of the limb in all cases with a limp that varied from slight to marked.

4 The abduction treatment is the method of choice but it can not be applied to all cases. There are people so decrepid that they can not be subjected to general anaesthesia and immobilization in a plaster spica without grave danger.

5 There is a type of intracapsular fracture in which one can tell in about two months if there is going to be no union. Such cases should not await radical procedure longer but be subjected to either a reconstruction or an autogenous bone graft.

## MEDICAL SOCIETY SALESMANSHIP

The Medical Society of the State of New York has many kinds of service to offer to its members. It is organized on the mutual plan. Its members govern the Society and share in its profits. The Society is what the members make it, and its profits depend on the amount of investment which the members put into it, and how well they manage it.

It is equally true that the profit which an individual member gets out of the Society depends on the amount of his investment in time and effort, and his intelligence in putting his investment to use. Dividend checks are not mailed to him—he must go and get them. He must take an interest in the activities of his Society—in its JOURNAL, in its meetings and clinics, in the work of its committees, and in its social gatherings.

One of the great problems of the leaders of the Medical Society of the State of New York is that of the salesmanship of plans. After they have studied a problem for weeks or months, and have devised an excellent solution, they must try to sell it to their confreres—and then the objections begin to roll in. Some don't like the name of the idea, and others ask if it works automatically and is foolproof. Some object to its cost, and others are just indifferent.

It takes salesmanship to convince the ten thousand members of the Medical Society of the State of New York. The two basic ideas underlying salesmanship are the printed advertisement and personal solicitation.

The principal advertising medium of the Medical Society of the State of New York is its

**JOURNAL** The **JOURNAL** contains the announcements of the officers and committeemen and the plans of the activities of the Society. Any one reading the files of the **JOURNAL** during the past year will find sufficient material to write a complete history of every activity of the Society. But while the **JOURNAL** is invaluable as a record, it lacks the element of repetition on which advertising success rests. It is not enough to make an announcement once, for it reaches only a small percentage of the people. It must be repeated over and over until a buyer cannot keep from saying "Gillette" when he wants a razor, and "Uneda" when he wants a biscuit, and the "County Medical Society" when he needs the help of a consultant.

What supplies the element of repetition in medical society salesmanship? A few county societies have their own publications which are efficient reminders of the activities of the society. There are also group societies, and organizations of specialists, and staff meetings of hospitals, all

of which remind the doctor of his duties in civic medicine.

The second element in salesmanship is personal contact with field workers. What would a manufacturing company do without its field agents who are always at the service of their customers to explain and demonstrate their wares. The officers and committeemen of the State Society have done their field work exceedingly well and have come into friendly contact with at least 50 per cent of the members throughout the State. Add to this the frequent contacts of the officers and committeemen of the District Branches and the county societies, and the aggregate makes a field force which is comparable only by that of the churches.

The machinery of the Medical Society of the State of New York is running smoothly and with increasing efficiency. But while the leaders will supply the material to feed the fires of inspiration and education, the rank and file of members must do the stoking.

## THE PITY OF IT

There is a peculiar psychology, somewhat general at the present time, in so-called "freedom of speech."

This land of ours has ever been tolerant and even over-zealous in seeing that the vociferous and loud-spoken should have all the air and opportunity necessary to relieve their overburdened chests. The law is particularly lenient in that it permits this exuberance even to the stage of insult, and strangely fortifies the abuser of freedom in giving him a ready access to the courts to combat and obtain damages, when an outraged citizen calls him by his right name.

The end result is rather unfortunate. A quack or charlatan, or even a misguided crusader, shouts out his noisy propaganda, reasonably sure that the respectable and orderly portion of the community will stand back rather than be caught in bad company. This accomplishes the desired result.

The purveyor of misstatement promptly becomes brazen, and bringing into play his extraordinary muscles of expiration he emanates the quadruple extract of all the departed martyrs. Yea, he takes upon himself the sorrows of the world, and in one fell jump he establishes himself as the leader of a crushed minority who would labor hopelessly but for his unselfish devotion. If the minority will keep the said martyr under careful observation and hand him enough rope, sooner or later adjectives will fail and he will state somewhat shyly "Now that the crowd is here, we will have a few words on Anti-Vivisection." He might also hand you a circular somewhat as follows:

"Are you going to submit to Medical Tyranny? A timely warning! Help save our Country from the Autocrats," etc. This outburst is the charlatan's protest against the law which requires a proper registration of physicians.

Another crew of malcontents don't want to be vaccinated. Still others don't believe in eating meat. One lurid pamphlet quotes with great gusto opinions of men so eminent that one had a title of M A, D C L, M R C S, and L R C P. A man with so distinguished a title don't need meat—he don't need anything except the great outdoors where men are men.

A gentleman by the name of A. Montagne under the title "A message to Cancer Patients. Why despair—Cancer is curable," gotten out over the name of the Maryland Anti-Vivisection Society has the following sentence in closing, "We should fail in a pressing duty were we to omit the mention of the C - T Treatment of Cancer" has proved itself successful in many cases, several of which are known to us."

What a boon to humanity—but how about the poor deluded person to whom this is sent, and believes in the brazen effrontery of the charlatan.

We question very seriously whether any well-balanced individual is mentally nimble enough to keep up with one who makes lying a profession—AND THERE'S THE PITY OF IT.

Abraham Lincoln, even in absentia, lends us a word of encouragement in his admonition "You cannot fool all of the people all of the time."

Were it possible to present these matters of health and public weal before all the people, there would still be a group of dissenters who, like a rotten apple, would insist on being present in the basket even though they contaminated their healthy neighbors.

It occurs to us that a profitable experience might be enjoyed by our Anti friends if all who could spare the time might summer in the pest house and learn at first hand the foolish fear of

smallpox, and in their leisure moments they might study what a great boon smallpox was in the middle ages—and then along came vaccination and as improvement in technique was developed, Europe was cleansed of a great scourge.

The children in the schools know this, and when the minds of these poor deluded Anti reach the growth of a child of ten, they will know it too.

There's the pity of it

---

## THERAPEUTIC STANDARDS

A small hospital with an open staff has difficulty in maintaining up-to-date standards of treatment. The staff usually includes all the doctors in the vicinity of the hospital, and they are general practitioners rather than specialists and original workers. While consultants are always available, yet they are not expected to be on call for every unusual case.

Every hospital is expected to exemplify the highest standards of therapeutic measures, and the members of the staffs are conscientious in their endeavors to give the patient the best possible treatment. The general practitioners are pretty well up in the newer discoveries. They can give insulin with intelligence, especially when they have the assistance of an expert laboratory technician. They know the indications for salvarsan, and can give it with expertness.

The medical limitations of the family doctor are along the lines of the general managements of the cases. What is the present accepted procedure in a case of vomiting of pregnancy? The older treatment involved the termination of pregnancy as an early procedure, but now rest and mental repose, and the use of water and glucose are the accepted therapeutic methods. But how shall these methods be carried out? Success requires much skill and attention to details.

Take the management of fevers as another illustration. We have all expected to see a dry tongue in pneumonia, but dryness of the mouth is a sure sign of dehydration with all its discomforts and dangers. The modern standards of practice require that water be given to those patients by mouth, by rectum, by hypodermoclysis, and intravenously until the tongue is moist and the kidneys resume their function.

Dehydration is accompanied by a deficiency of

sugar in the blood, with its train of acidosis from the imperfect utilization of fats and proteins. The modern standards of medical treatment require the administration of glucose or sugar to fever cases with dry tongues. How it shall be given—by mouth, by rectum, or intravenously—will depend on the indications of the case and the skill of the doctor.

How can a hospital attain a high grade in the management of cases?

The hospital staff might adopt standard methods either formally or informally.

The hospital might adopt a system of General Rounds by the entire staff once every week or month. Patients and doctors would all be benefited if every case were seen periodically by the entire staff.

Each member of the staff might be appointed to perfect himself in some particular line. No one can attain a high grade in all lines of medicine, but every doctor can attain a high grade in some line.

Articles might be prepared and published in the medical journals on practical subjects that are not covered by text books.

Every small hospital can be a center at which a very large proportion of the doctors in its vicinity can learn to practice up-to-date methods. Not all that is up-to-date centers in the laboratory. Any doctor can order a test made and get it done if an interne and a laboratory technician are available. The greatest need of every hospital is that its staff should develop increasing skill in the art of caring for its patients.

Therapeutic standards are set forth by the American College of Surgeons, and are well within the reach of even small hospitals.

# MEDICAL SURVEY

## MEDICAL SURVEY NUMBER 16—CAYUGA AND SENECA COUNTIES

**EDITOR'S NOTE** The information on which the survey of Cayuga County is founded was obtained principally from Dr A J Bennett, President of the Cayuga County Medical Society, and Dr G F Ross, Secretary, Dr A K Bates, Dr T C Sawyer, Health Officer of Auburn, and Dr F W Sears, District State Health Officer.

Cayuga County lies on the east side of Cayuga Lake. It extends south for about 55 miles from Lake Ontario, and lies about one-third of the way from Syracuse to Rochester. Its frontage on Lake Ontario is only ten miles, and its width at its southern end is about twenty-five miles. Its area is 703 square miles. Its surface is rolling, and fruit farming is one of its important industries.

The population of Cayuga County was 65,221 in 1920, which is about 2,000 less than in 1910, and only 10,000 greater than in 1850. Yet the people are prosperous and progressive.

The County has only one city, Auburn, which has a population of 36,192. It has only three villages with populations over 1,000: Moravia, population, 1,331; Port Byron, 1,035; and Weedsport, 1,379. There are 6,333 people dwelling in incorporated villages, and 22,696 living in the strictly rural sections.

**Physicians**—There are 82 physicians listed in the County by the Medical Directory of the Medical Society of the State of New York. They live in 17 centers—55 physicians in Auburn, and 27 in the rest of the County. Auburn has one doctor in every 650 population, and the rest of the County, one in 1,100 people.

Auburn is the medical center of Cayuga County, and is also the center politically and geographically. Good roads extend through every part of the County, and transportation is easy. The doctors in the extreme north end of the county go to Oswego and Syracuse for hospitals and consultants, and those in the south end patronize the hospitals in Ithaca and Cortland, but most of the county cases of sickness go to the Auburn hospitals.

**Hospitals**—Cayuga County has two hospitals, both in Auburn.

The Auburn City Hospital was founded in 1878 and has 85 beds, but a million-dollar addition now under construction will give it a capacity of 150 beds. The hospital is privately supported, although it is called the "City Hospital." It is a general hospital with services in medicine, sur-

gery, obstetrics, and eye, ear, nose and throat. It has an appointive staff, but nearly all the doctors in the city are on it. Two internes are employed, monthly staff meetings are held, and the standards of the American College of Surgeons are observed. A history clerk is employed, and a training school with 50 pupil nurses is maintained. It also has a laboratory and an X-ray department. It is planned to add an outpatient department to the new hospital.

Mercy Hospital was opened five years ago. It has 25 beds, and conducts a training school for nurses.

The City of Auburn maintains a tuberculosis hospital with 20 beds.

Cayuga County has 2 hospital beds in every 1,000 population, but when the addition to the City Hospital is completed, it will have 25 beds in every 1,000 population. But since hospitals in adjoining counties are used, a full quota of hospital beds is available.

**Medical Societies**—The Cayuga County Medical Society has 62 members, which includes over 75 per cent of the physicians listed in the county. Monthly meetings are held, usually in Auburn. The attendance at the meetings averages over 20 members.

Auburn formerly had an academy of medicine, but it was discontinued when the staff meetings of the hospital were instituted about five years ago.

**Public Health Work**—The official public health work of Cayuga County is done in 30 districts which are served by 20 health officers. Each health officer outside of Auburn City serves an average of 1,500 people.

Seventy per cent of the doctors outside of Auburn are health officers, and 75 per cent of the health officers have taken special courses of instruction.

The health officer of the City of Auburn, Dr T C Sawyer, gives nearly all his time to the office. His outstanding accomplishment has been the suppression of endemic diphtheria by the use of the Schick test and immunization with toxin-antitoxin. Nearly every school child and many of the pre-school age have been immunized. The work is being actively continued in the schools, and public sentiment is overwhelming in its favor.

A health center is maintained in the Neighborhood House, where prenatal, child welfare, men-

tal hygiene, and dental clinics are conducted. A venereal disease clinic and one in tuberculosis are conducted by the city.

The city water is filtered, and bacteriological examinations are made regularly. The water ranks among the purest in the State.

The only grades of milk permitted to be sold in Auburn are pasteurized and "Grade A" raw.

Tuberculosis work in Auburn is done by a special city nurse. The city maintains a tuberculosis hospital with 20 beds, but none is maintained by the county. The county employs a tuberculosis nurse.

School medical inspections are well conducted, and toxin-antitoxin immunizations are done to a greater extent than anywhere else in the State.

The county has a tuberculosis committee whose work is maintained by the sale of Christmas Seal Stamps.

*Public Health Nurses*—There are seven public health nurses employed in Cayuga County, as follows:

County nurse  
Weedsport Community Nurse  
Auburn Board of Health  
Auburn schools  
Red Cross at Auburn, Bedside  
Metropolitan Life Insurance Company  
Auburn Neighborhood House

*Impressions*—We talked with a number of physicians of Cayuga County during the meeting of the Seventh District Branch, and were impressed with their sense of civic duty. A small city that will build a million dollar hospital for the use of its doctors generally has confidence in its physicians and in their spirit of civic service.

## SENECA COUNTY

*EDITOR'S NOTE* The information regarding Seneca County was supplied principally by Dr. F. W. Lester, Past-President of the Seneca County Medical Society, and Dr. William M. Follett, the present Secretary.

Seneca County adjoins Cayuga County on the west. It fills the rectangle between Cayuga and Seneca Lakes, and is 35 miles long and 15 across at its widest part. It has an area of 336 square miles, nearly all of which is devoted to fruit and general farming, but two large pump manufacturing works are located in Seneca Falls, employing about 1,500 to 2,000 operators. The lines of travel are north and south, for the lakes limit it east and west. The civic center of the county is Waterloo, the county seat, located at the north end of the county.

Seneca County had a population of 24,735 in 1920, but in 1850 there were 25,441 people living in the country. This decrease in population is explained by the fewer number of people required to till the farms owing to the present use of machinery. The county is now more prosperous than ever.

The centers of population are four villages with a total population of 11,269. The two villages having populations over 1,000 are Seneca Falls, population 6,389, and Waterloo, population, 3,809. The number of people living outside the villages is 13,466.

*Physicians*—There are 33 physicians in Seneca County listed in the Medical Directory of the State Society, of whom 8 are on the staff of the Willard State Hospital and the rest are located in seven centers. If the physicians in the State Hospital are not counted, each physician serves an average of 1,000 people.

*Hospitals*—There are two general hospitals in Seneca County. 1. That in Seneca Falls. It has 25 beds. It has an open staff, which holds a monthly meeting. It has a laboratory in which the physicians and nurses examine specimens. It is owned and operated by the Township of Seneca Falls. 2. Waterloo Memorial Hospital at Waterloo, N. Y., is an open hospital with 15 beds.

While Seneca County itself has only 16 beds for every 1,000 people, yet the people are within easy reach of hospitals in Auburn, Geneva and Ithaca, and so have hospitals available for all cases.

*Medical Society*—The Seneca County Medical Society has 26 members, which is 75 per cent of the physicians listed in the County. It holds two meetings annually, and the average attendance is between 15 and 20 members.

Many of the doctors of Seneca County are regular attendants at the monthly meetings of the Academy of Medicine in Geneva, which is only a few miles beyond the western boundary of Seneca County.

*Public Health Work*—The official public health work of Seneca County is done by eight health officers, every one of whom belongs to the County Medical Society—an enviable record. Six of the health officers have taken a special course of instruction. Each health officer serves 3,000 people—a high average.

The county supports a tuberculosis nurse, and Seneca Falls has a school nurse.

*Impressions*—Seneca is a rural county, lying between two lakes, and having close connections with its neighbors on the north and south. Its doctors are progressive, and are ready to cooperate in Graduate Education.

# DISTRICT BRANCHES

## SIXTH DISTRICT BRANCH

The annual meeting of the Sixth District Branch, which is composed of the Counties of Broome, Chenango, Chemung, Cortland, Delaware, Otsego, Schuyler, Steuben, Tompkins, and Tioga, was held on October 6, in the Bank Auditorium, Ithaca, the President, Dr George H Fox, of Binghamton, was in the chair, and 85 members were in attendance. About twenty ladies accompanied the doctors.

The following officers were elected for the next two years

### President

Dr Wilber G Fish - - - - - Ithaca

### First Vice-President

Dr LeRue Colegrove - - - - - Elmira

### Second Vice-President

Dr George M Cady - - - - - Owego

### Secretary

Dr Hubert B Marvin - - - - Binghamton

### Treasurer

Dr Stuart B Blakely - - - - Binghamton

Two sessions were held, with a recess for lunch, which was served in the room adjoining the meeting place.

Dr N B Van Etten, President of the Medical Society of the State of New York, gave an address on the principles and objects of the society. He called special attention to the need of medical insurance and to the graduate education plans of the State Society.

Dr Daniel S Dougherty, Secretary of the State Medical Society, addressed the society on the details of a Secretary's work. He said that a permanent secretary is invaluable to a county society, and while presidents come and go, a society does well to keep its secretary in office year after year.

Dr Dougherty spoke of the introduction of business methods of the State Medical Society. The Society now has an income of \$100,000 annually and a proposed amendment to the by-laws, to be acted on at the next annual meeting, provides for a permanent Board of Trustees that will manage the finances of the Society.

The Doctor also advised the doctors to read the Journal, for it contains a record of the various acts and activities of the State and every respect

County Societies. He also referred to the value of the advice of Mr Whiteside, the Counsel of the State Society, and mentioned the legal point that a doctor who in the kindness of his heart, assures a patient of a quick recovery, is liable for damages in the event of death.

The scientific program was as follows

Infections and Mental Disease—Dr William C Garvin, Superintendent of the Binghamton State Hospital

The Clinical Interpretation of the Wasserman Test—Dr W Avery Groat, Syracuse

The Use of Sodium Iodide in Focal Infections—Dr James W Wiltsie, Binghamton

The Accessory Nasal Sinuses (Illustrated with Specimens)—Dr Abram T Kerr, Professor of Anatomy, Cornell University Medical School

A Case of Chronic Juvenile Lenticular Degeneration (Wilson's Disease) (Illustrated with Lantern Slides)—Dr James W Papez, Department of Neurology, Cornell University

The Influence of the Thyroid on Structure and Function in Sheep and Goats (Illustrated with Motion Pictures)—Howard S Liddell, Ph D, Department of Physiology, Cornell University

Dr Garvin described cases of insanity that were caused by infective and exhaustive states with which general practitioners had to deal in the early stages of the mental conditions. He made a plea for a greater consideration of psychiatric states by the family doctor. The staff of the State hospitals go out to several cities in order to conduct clinics at which physicians are welcome. Plans are also being considered to bring fundamental instruction in psychiatry within reach of the family doctors.

Dr Liddell's motion picture talk was on the effects of the removal of the thyroid gland from young sheep and goats.

Moving pictures were exhibited showing the physical weakness and mental dullness of the abnormal sheep and the stimulating effects of thyroid extract given to animals.

The meeting was unusually successful in

## NEWS NOTES

### MEDICAL SOCIETY, COUNTY OF QUEENS

A regular meeting of the Medical Society of the County of Queens was held Tuesday, September 29, 1925, at the Eagle Palace, Jamaica, at 8 30 P M, with the President, Dr Courten in the chair After the minutes of the previous meeting had been read and approved, the following candidates were elected to membership

Doctors James I Schoonmaker, John P Scheneble, Joseph J Schanno and Henry George Peter

Dr Thomas C Chalmers then gave a brief resume of the new medical practice act, framed by the committee of the State Medical Society to be presented to the legislature at its next session

The secretary, in accordance with instructions of the Comitia Minora read the following recommendations (1) a report of the Committee on Illegal Practice of the Department of Health, relative to the Lincoln X-Ray Laboratories, 32 162nd Street, Jamaica and of an investigation of a physician, Dr A S Bughee of Manhattan, one of the proprietors of the laboratories mentioned, (2) a letter from the Queens Council Boy Scouts of America, thanking the society for medical service at Camp Matinecock during the summer, and requesting volunteer physicians for the summer of 1926, and (3) an announcement from the *New York State Medical Journal* of the appointment of Mr Joseph B Tufts as advertising manager, with offices at 17 West 43rd Street, New York City, and a request for individual physicians to approach patients and friends dealing in commodities of interest to physicians, with a view to increase the amount of advertising in the *Journal*

Dr C S Prest, Executive Secretary of the Queensboro Tuberculosis Association made a brief announcement of the motion picture, "Working for Dear Life" now being exhibited by the initiative of his association and blanks for health examination to physicians

He also mentioned the facilities of the association to supply information to physicians relative to sanatoria for tuberculosis patients

In the Scientific Session, in the address by Dr Frank D Jennings, on "Graduate Medical Education" A history of the development of the movement for graduate medical education in Kings County was given, including the Friday afternoon lectures and the work of the Joint Committee for Graduate Medical Education of the Long Island College Hospital and the Kings County Society Dr Jennings emphasized the obligation resting upon organized medicine to promote education of the profession, and showed that the Kings County Society had sensed the need, opportunity and duty Instruction must be fundamental, basic and designed to help individual physicians in the solution of every day problems He also showed that general hospitals can be made teaching centers, available to all physicians in their districts, not merely to the members of its staffs

Dr Thurston Welton of Brooklyn, discussed briefly the address of Dr Jennings

Dr Walter J Highman of New York City, in his talk on "Common Sense in the Management of Syphilis," commented on the complexities concerning the disease, resulting from recent addition to laboratory methods of diagnosis and to the armamentarium for treatment In spite of complexities, a large share of the treatment of syphilitic patients must be undertaken by the general practitioner because qualified specialists are not available for many cases, nor are they necessary in all cases Diagnosis is usually not difficult, and the laboratory will clean up 90% of the doubtful cases In simple every day aspects, the problems of treatment can be met by the general practitioner Dr Highman cited instances where the exercise or lack of exercise of broad common sense was the determining factor successful or unsuccessful issue of the case There was an attendance of 70

### TOMPKINS COUNTY MEDICAL SOCIETY

The September meeting of the Tompkins County Medical Society was held in the Ithaca Chamber of Commerce parlors Tuesday evening the 15th, with about 40 members and visitors present. President John W. Judd in the chair.

This being the first regular meeting since May the minutes of the May meeting were read and approved, also those of the joint meeting with the Cortland County Society in June.

The report of the Comitia was made by reading its minutes.

A communication was read from Dr. Joseph S. Lawrence, Executive Officer of the State Society, suggesting that County Medical Societies deposit any historical relics and old minute books they may have, in the State Medical Library at Albany for safe keeping. This society, having deposited its first record book in the Cornell University Library, it was moved and carried that it be left there for the present.

A communication was read from Dr. Orrin S. Wightman, Editor, *New York State Journal of Medicine*, suggesting that members of County Medical Societies solicit, in their ter-

ritory, advertising for the State Journal, the object being to double such advertising for the coming year.

It was moved and carried that this matter be laid upon the table.

The application of William M. Maloney, M.D., for membership was presented and being endorsed by the Censors he was duly elected.

The request of the State Department of Health that this society suggest such of its members as will be willing to conduct clinics for pre-school children in this county, was presented, and it was moved and carried that Dr. Helen D. Bull be so designated.

The President appointed Drs. Luzerne Co-ville and Henry B. Sutton a committee to present at the next meeting suitable resolutions upon the death of Dr. Jennie G. Seeley.

Arthur L. Holland, M.D., of New York, presented a very interesting and instructive paper on the subject of "Gastric Ulcers" which received the close attention and interest of all present, bringing out a rather full discussion and many questions. After a rising vote of thanks to Dr. Holland the meeting adjourned for lunch.

---

### ORLEANS COUNTY MEDICAL SOCIETY

The regular annual meeting of Orleans County Medical Society was held at Lone Star Inn, Albion, at 4 p. m., Tuesday, September 29, 1925.

The following officers were re-elected for the ensuing year: La Verne F. Waters, Medina, President; John Dugan, Albion, Vice-President; J. K. Durling, Albion, Secretary-Treasurer; Geo. F. Rogan, Medina, John Sutton, Albion, J. F. Eckerson, Shelby, Censors; Delegate to State Society, Dr. J. F. Eckerson, Shelby; Alternate, Dr. R. E. Brodie, Albion.

Dr. J. Arthur Elson was elected to membership.

Dr. Joseph S. Lawrence, Executive Officer of the State Medical Society, gave a talk on "Congenital Syphilis," and illustrated the talk with lantern slides. Dr. Lawrence also spoke on the functions of the county and state society from the standpoint of service to the doctor and the public.

Fourteen members and one guest were present. Dinner was served in the dining room of the inn.

# THE DAILY PRESS

Doctors can offer toxin-antitoxin to the public, but the people will not take it unless they are strongly impressed with its need. There are several methods of educating the people to take the preventive against diphtheria. Dr. William H. Park was the first to demonstrate the practicality of utilizing the schools for giving it to the pupils. The State Department of Health used that method successfully to suppress an epidemic of long standing in the city of Auburn. There, the unusual number of deaths in spite of the use of all the common means of prevention led the school authorities to advocate the administration of toxin-antitoxin to all the children. The imminent danger from a great number of carriers impelled the people almost unanimously to consent to the immunization of the school children. And Dr. Sawyer, the Health Officer, is now having no difficulty in immunizing the young children who are entering school for the first time. (See this Journal, page 973.) The anti-vaccinationists and other unscientific propagandists have probably utilized more newspaper space than doctors and departments of health have used in advocating the serum immunizations, but the tide has turned, and people generally are being educated.

Whenever the immunization of school children has been advocated, a campaign of education has been necessary in order to get the people to consent to its use on their children, and the newspapers have been the principal means of carrying information to them and inducing them to accept the procedure. The toxin-antitoxin campaigns that have been conducted in the smaller cities by the State Department of Health have been excellent demonstrations of the value of newspaper publicity in the medical education of the people.

The diphtheria epidemic in Nome, Alaska last winter afforded an opportunity to do the most effective piece of medical education that had ever been presented through the newspapers. The story of the race to carry antitoxin to the stricken city was as dramatic as that of the rescue of the crew and passengers of a sinking ocean liner, and was fully utilized by the newspapers day after day. The unusual human interest of the story—the dire need of dying children, and the heroic dash of a hundred miles over the snow through an Arctic night—led millions of people to follow the newspaper accounts day after day up to its culmination in the relief of the epidemic.

Contrast this story with that of the story of alleged danger from frozen antitoxin that had been featured in the newspapers only a few months earlier. The antitoxin that was carried

to Nome was frozen in the incredibly low temperature of sixty degrees below zero, and yet it was safe and effective.

When William J. Shannon started on the first stretch of the journey, he set an example which drivers of other dog teams were glad to emulate. Nothing except the compulsion of his own conscience led him to start with his noble dogs at nine o'clock at night to carry the antitoxin sixty miles through the most bitter cold imaginable, and there were others just as heroic as he to continue the journey.

It was fortunate that Shannon was willing to come to New York State with his dog team at the solicitation of public spirited citizens, and lend his influence to toxin-antitoxin campaigns. That he should do this was as proper as that Dr. Grentell should come from Newfoundland and lecture to large audiences who were attracted by his fame as a self-sacrificing physician ministering to a people in dire need. We understand that Shannon is a kindly, modest man, as are all true heroes and lovers of their fellow men.

We are impelled to write this introduction by the receipt of a clipping from the *Olean Times* of September eleventh, describing the visit of Shannon to Olean and the neighboring villages of Cattaraugus County. We believe that the following account from the newspaper is a model as an effective piece of medical publicity.

"William J. 'Bill' Shannon, famous Alaskan 'musher,' who started the antitoxin for diphtheria stricken Nome on the initial part of its eight hundred mile journey was greeted with a great ovation when he appeared in this city today with his 'huskies.' He arrived in the city at eleven o'clock this morning and drove the team to St. Mary's school where a large number of school children and men and women were assembled.

"Prior to the arrival of 'Bill,' toxin-antitoxin was given to seven pupils. The toxin-antitoxin is an absolute preventive of diphtheria while the antitoxin is a cure. It was the antitoxin that was carried to Nome by the Alaskan mushers.

"Shannon was introduced by John Armstrong of the county health association and gave an interesting account of his journey over the frozen snows of the far north. He said:

"'Nome, an isolated town eight hundred miles from the nearest railroad center, Chenana, was stricken by diphtheria and the only possible cure was antitoxin. I was in Chenana at the time and volunteered my dogs and myself to the aid of the stricken people. The antitoxin arrived on the railroad at Chenana and I was there ready

to start I wrapped up my precious package in two furs and a canvas and loaded it on my sled. That was nine o'clock at night. I started at once for the next nearest station, which was sixty miles, and where there was another team ready to carry on.

"When I started it was 50 degrees below zero and I rode for a few miles. When the thermometer drops below 40 degrees, a frost fog settles over the country and it was through this fog that I had to go. It was so dense that I couldn't see my dogs ahead of me, but I knew that my head dog, "Blackie" could guide me through all right as he had been over the same trail many times before.

"After a time the cold became so unbearable that I walked ahead of the team. I was afraid to run behind them because I feared my lungs would freeze and that would cause bleeding of the mouth and eventual death. I finally reached a little road house, the only one between my starting and stopping points.

"After some effort, I aroused the owner and told him to make me a pot of coffee in a hurry. While the coffee was being made, I sheltered my dogs in a lean-to and found that three of them had frozen lungs. I took the antitoxin and placed it among the rafters in the house to let it warm through. After drinking five or six cups of steaming black coffee, I continued on my journey, leaving the three frozen dogs behind.

"I treaded ahead of the team for the greater part of the twenty-eight miles to the station where another team took up the journey. All

of the last part of the trip was made with the thermometer hovering about the 60 degree below mark. I arrived at the station at about eleven o'clock in the morning. My hands and feet were frost bitten and my face was stiffened from the intense cold."

"The dogs that Shannon has with him are part of the team that he used on his heroic trip. The three that were frozen died, but will long be remembered by the citizens of Nome. The trip to Nome was made in five and one-half days. The best time that had been made prior to that was fifteen days, according to Shannon.

"Toxin-antitoxin was also administered to five children at the city hall this noon after which the team departed for Franklinville, where they are scheduled with their master to stage a demonstration before the school children and community. The toxin-antitoxin taken to Franklinville was given to Shannon by Dr. Stephen A. Douglas at St. Mary's school this morning amidst the cheering of hundreds of school children."

History is mostly biography, and current history in the newspapers is always written around some person (see this Journal, August, 1925, page 888). Shannon's contribution to the toxin-antitoxin campaign is based on his thrilling experience which will always make a compelling appeal to all persons, especially to children. Wherever he appears, his presence is a sure antidote for anti-vaccinationist propaganda, and an inspiration for the acceptance of immunization against diphtheria.

# BOOK REVIEWS

**INFANTILE PARALYSIS IN VERMONT, 1894-1922** A Memorial to Charles S. Caverly, M.D. Octavo of 375 pages. Burlington, Vt., State Department of Public Health, 1924

Many will recall that the first epidemic of Infantile Paralysis in this country, occurred in the Otter Creek Valley of Vermont, during the summer of 1894. Dr. Charles S. Caverly, who had been president of the Vermont State Board of Health since 1891, sensed almost immediately the seriousness of the malady. His untiring efforts in a State-wide campaign resulted in the collection of valuable data which was made the basis of an article in the December 1894 issue of the "New York Medical Record."

During the following 24 years with Caverly still at the helm, additional data was collected. In 1914, the most serious outbreak took place, creating a serious problem. His vision was broad—through his efforts an anonymous friend of the State donated a considerable sum of money for the study of the cause and treatment of the disease, from Boston he summoned the late Dr. Robert Lovett while from New York he sought the advice of Flexner and others.

The outcome of their combined efforts is known to all who even have a passing interest in this disease. Much was contributed to the epidemiology by the laboratory workers, a survey of the cripple problem was made—clinics were established at various centers, field workers were trained in details of after care, a brace shop organized and the afflicted frequently re-examined.

All this did Caverly see—in his 27 years as President of the Board—and in September, 1918, passed to the Great Beyond, with his dreams unrealized, but with his heart gladdened by the progress made. How cheered would he have been to have seen the establishment of Kimball Cottage in Boston, where the operative phase was carried on—or to have witnessed the opening of Ormsbee House, a school for the exclusive use of cripples, at Proctor, Vt.<sup>1</sup>

This is a splendid memorial volume. The State of Vermont may well extol Caverly's greatness and add a solemn note of regret for the recent passing onward of that other benefactor to the Green Mountain State, Dr. Robert W. Lovett, of Boston.

DONALD E. MCKENNA

**THE HUMAN TESTIS, ITS GROSS ANATOMY HISTOLOGY, PHYSIOLOGY, PATHOLOGY, WITH PARTICULAR REFERENCE TO ITS ENDOCRINOLOGY, ABERRATIONS OF FUNCTION AND CORRELATION TO OTHER ENDOCRINES, etc.** By MAX THREEK, M.D., Surgeon-in-Chief American Hospital, Consulting Surgeon, Cook County Hospital, Chicago, Ill. 308 illustrations. J. B. Lippincott Co. Phila., 1924.

In this volume the author has endeavored to present all the information obtainable from various textbooks and scientific publications in English and foreign languages on the important subject of the testis. This book is a compact work that embraces and elucidates the important questions relative to the anatomy, histology, physiology, pathology, dystrophias, endocrinology, aberration and other important questions concerning the human testes.

A number of questions relative to the various phases of this work are still unsettled and controverted, especially concerning the endocrinology of the testes. Many of the statements in medical publications are founded as the result of chemical research,

while other are exaggerated, and not based on facts and thereby do more harm than good. Many of the conclusions embodied in this volume are the results of a combination of personal observations associated with laboratory research. All obtainable data contained in the literature as a contribution of other workers have been brought down to date. Relative to the endocrinology of the testes, the author publishes his own findings, and also the surgical application of knowledge gained on sex gland transplantation and all the obtainable data on this phase of the work by his personal acquaintance and communication with many of the investigators in this field of research. There is a full bibliography and many photographs of gross specimens and microphotographs illuminate the text. On the whole, a very readable and complete treatise on the subject.

PHILIP GOLDFADER.

**FIRST STEPS IN ORGANIZING A HOSPITAL. AN EXPOSITION OF IDEALS AND PRINCIPLES INCIDENT TO THE INCEPTION AND ORGANIZATION OF A HOSPITAL.** By JOSEPH J. WEBER, M.A. Editor, *The Modern Hospital*. The Macmillan Co., New York, 1924.

This book would scarcely appeal to those who have given the subject any consideration but may serve a useful purpose to an enthusiastic but uninformed group in attempting to organize a hospital.

The medical profession would no doubt be represented on the committee and would have rather definite ideas of organizing their end of the proposed hospital rather than follow the form laid down in this book. Why pad the book with some sixty pages of examples of forms according to the laws of Illinois, examples of by-laws, form of agreement with architect, etc.?

R. E. S.

**THE SCIENCE AND ART OF ANESTHESIA.** By COLONEL WILLIAM WEBSTER, D.S.O., M.D., C.M., Professor Anesthesiology, University Manitoba Medical School, Chief Anesthetist, Winnipeg General Hospital. Illustrated. The C. V. Mosby Co., St. Louis, Mo. 1924. Price, \$4.75.

As a teacher of anesthesia Dr. Webster has probably felt the need of a brief outline of his subject, and his students, as they have passed through his course year after year have been aided by the use of it. The little paper-covered syllabus we can still remember as one of the essentials of the medical course, it concisely epitomized the subject in a few pages. But why not allow the work to remain in the informal dress of the syllabus instead of making it into a large book by the familiar methods of the publisher?

The subject matter is orthodox. The author's experience as a pathologist has undoubtedly added to his inherent interest in the chemistry of the subject. The chapter on physiology is brief but clear and the discussion of the subjects of shocks, acidosis, the estimation of cardiac strength and the relation of temperature and humidity to postoperative recovery show the marks of practical experience.

The chapters on ethyl chloride in a favorable light and of chloroform in a rather deprecatory way are given more space than usual. As a whole, the book fulfills its purpose of being a sound, sensible guide to the student and the general practitioner in the choice and administration of an anesthetic.

G. W. TONG.

to start I wrapped up my precious package in two furs and a canvas and loaded it on my sled. That was nine o'clock at night. I started at once for the next nearest station, which was sixty miles, and where there was another team ready to carry on.

"Toxin-antitoxin was also administered to five children at the city hall this noon after which the team departed for Franklinville, where they are scheduled with their master to stage a demonstration before the school children and community. The toxin-antitoxin taken to Franklinville was given to Shannon by Dr. Stephen A. Douglas at St. Mary's school this morning amidst the cheering of hundreds of school children."

History is mostly biography, and current history in the newspapers is always written around some person (see this Journal, August, 1925, page 888). Shannon's contribution to the toxin-antitoxin campaign is based on his thrilling experience which will always make a compelling appeal to all persons, especially to children. Wherever he appears, his presence is a sure antidote for anti-vaccinationist propaganda, and an inspiration for the acceptance of immunization against diphtheria.

rative well shows. The book is written in the scientific manner, but in very readable form for the layman

Lister was early impressed with the destructive consequences of suppuration, and at once began the study of its causes and possible prevention. No flight of scientific inspiration led him to his theory of antiseptics, but step by step he worked up to the demonstration of the value of antiseptics, notably carbolic acid. Other problems in wound healing were patiently worked out by him, especially that of the absorbable ligature, resulting in the use of catgut, properly prepared.

The story of Lister's success provides inspiration and example to every young surgeon. His education and training were from the start on broad and scientific lines. At no time was he diverted from his great interest in his profession or his purpose to work up into the higher places in Surgery, then a much smaller field than today. His expressed high ideals in his work, his gentleness in the handling of patients, the beautiful touches of family life as shown in his correspondence, all indicate the great refinement of his nature.

It is to be hoped that a special edition of this work may be brought out at a low price, to bring it more widely into the hands of physicians and students

R. W. W.

**INSULIN IN GENERAL PRACTICE. A Concise Clinical Guide for Practitioners.** By A. CLARKE BEGG O.B.E. M.D., Ch.B., M.D. 12mo of 130 pages, illustrated. London, William Heinemann, 1924 Cloth, 5s

The book is well described by the title and gives a very good general idea of the principles of treatment of diabetes mellitus

The usual laboratory tests are first described, MacLean's method of blood sugar estimation being given. The author still occasionally uses Graham's ladder diet but generally follows what seems to be the best procedure at present, that is, to give the patient a maintenance diet and see how he handles it. The average patient who is not confined to bed is given a diet of about 2,300 calories of carbohydrate 70 grams, protein 80 grams and fat 185 grams. This diet the author calls the "Standard" diet and states that a few can do with less and some require more. A fast day once a week is recommended. A number of standard diets are given attention being given to the cost. Nearly all provide for the English afternoon tea.

The standard diet given seems higher than is often necessary except for a man doing physical work, as many patients are satisfied, maintain a proper body weight and can do without insulin on diets of from 1,700 to 2,000 calories. This is especially true of rather elderly and obese patients.

The closing chapters describe the treatment of acidosis coma and gangrene. The book is highly recommended as an excellent guide and gives in a brief manner a very good idea of the subject

W. E. McCOLLUM

**TEXTBOOK OF DIFFERENTIAL DIAGNOSIS OF INTERNAL MEDICINE.** By M. METTHES M.D. Authorized translation of the fourth German edition with extensive additions by I. W. Held M.D. and Mr. H. Gross M.D. Royal octavo with 908 pages with 176 illustrations. Phila. P. Blakiston's Son & Co. 1925 Cloth \$12.00

With this translation of the fourth German edition this excellent textbook makes its first appearance in English. The author has the faculty of presenting his subject in an accurate, compact and practical form easily read, understood and retained. The subject matter includes apparently all useful information concerning the differential diagnosis of related or confusing conditions. The translators have added to the value of the volume by presenting their own comments and opinions and giving also the American view of many diagnostic points. The book is printed upon heavy paper in easily read type, and is well illustrated. This is a valuable book not only for reference but for information and study.

HEURY M. MOSES

**CLINICAL MEDICINE FOR NURSES.** By PAUL H. RINGER, A.B.M.D. Second Edition, revised. 12mo of 306 pages, with illustrations. Phila., F. A. Davis Co., 1924 Cloth, \$2.50

This book represents the substance of a series of lectures delivered for several years at the Asheville, N. C. Mission Hospital. Symptoms and their meaning and complications have been treated rather than bacteriology and pathology, as the author states in the preface.

All the common diseases are described in a brief manner. The volume is a very good one for the use of training schools which give a full course.

W. E. McC.

**DISEASES OF THE HEART.** By Dr. HENRI VAQUEZ. Translated and edited by GEORGE F. LADLAW, M.D. Octavo of 743 pages, illustrated. Philadelphia and London, W. B. Saunders Company, 1924 Cloth, \$3.50

Vaquez's introduction of twelve pages so faithfully sketches the steps in study and investigation of cardiac disease, by which we have reached our present day conceptions, and is so finely done that it not alone constitutes a valuable feature of his volume but it sweeps the ground from under the feet of those who would spurn the lessons of the past and neglect to acknowledge the debt of modern medicine to the masters now gone.

We pick up this book hoping to gain a view of cardiology from the French standpoint and we are not disappointed. Vaquez has done his utmost to give us comprehensively the French story of heart disease in its various phases, and while he naturally stresses the contributions of his Gallic compatriots, it cannot be said that he neglects the facts of research as developed in other countries.

The volume has riches in every chapter, and not the least is the full bibliography at the end of each.

Every cardiologist writes with a certain classification in mind and it is interesting to note that Vaquez follows the anatomic grouping although he stresses etiology throughout. This arrangement is outstanding, when we consider the etiologic grouping of the Boston school and the physiologic classification of the English writers.

The style is inviting. Thayer in his introductory remarks comments on the graphic description of angina pectoris, and this chapter is typical of the book. Prolonged Subacute Endocarditis is a subject that is characteristically well presented, and here American investigators receive special notice.

Syphilis of the heart is accorded discussion in the compass of 14 pages, and would possibly merit more extended remarks when the size of the book, 743 pages, is considered. Radiology is discussed in 15 pages and is a subject in which the investigations of the author are noteworthy, Bordet being a co-worker in the studies. Eighteen pages are devoted to the electrocardiograph, and here Vaquez emphasizes the point that bedside observation still outweighs laboratory diagnosis.

Blood Pressure is discussed in a chapter of 28 pages and Arterial Hypertension in an interesting chapter of 32 pages. The author summarizes his views by stating that hypertension is the result of over-activity of the chromaffin system renal and vascular lesions appearing later.

Gallop rhythm is held to be due to vibration of the degenerated ventricular wall dilating suddenly in early diastole. The opinions of the distinguished author are given with considerable emphasis, although he modestly states that the "book is probably incomplete, but in it I have at least said all that I know."

In treatment, discussion is thorough and Strophanthus receives kinder criticism than is usual in America. These final chapters round out a volume of great value, which it is a privilege to have translated into English.

FRANK BETHEL CROSS

**THE CHILD-HEALTH LIBRARY** A Series of ten books by practicing specialists Edited by JOHN C GEBHART Pocket-size volumes, published by Robert K. Haas, Inc., New York. 1925 Price of set, with book-ends, \$3.00

**Vol. I Prenatal Care and the Baby's Birth** By Harbeck Halsted, M.D. In the introduction by Haven Emerson, M.D., occur these words, which are a fitting commentary on the series "Health is as personal as work or play, however much we may hear of public health, public health works, and the public playground"

So the authors of these health stories have acted, as it were, like honest trustees of science, and are putting before you, the beneficiaries of all knowledge, the information you need to bring to you and yours, health, and perhaps (with it) beauty of person and character"

**Vol. II Babies—Their Feeding and Care** By Louis C Schroeder, M.D. This is a valuable short summary for the mother interested in the ordinary diet and hygiene of babies up to two years.

**Vol. III The Neglected Age. The Child from Two to Six.** By Bernard S Denzer, M.D. This includes diet, games, books, and mental hygiene.

**Vol. IV Dangers of the School Age.** By Alice Asserson, M.D. Among other things are given some of the symptoms that may be a warning to the mother of the onset of an acute illness.

**Vol. V Communicable Diseases of Childhood.** By Stafford McLean, M.D. A short, readily understood summary of infection and immunity precedes the individual diseases.

**Vol. VI Hygiene of the Mouth and Teeth** By Thaddeus P Hyatt, DDS. The advice given for lancing the gums seems like returning to the good old days of fifty years ago, and if the child is in the hands of a competent physician it will be spared this unnecessary pain.

**Vol. VII What Children of Various Ages Should Eat.** By Lucy Gillett, M.A. Caloric values interpreted in terms of common measure bring caloric feeding to any mother.

**Vol. VIII How Children Ought to Grow** By John C Gebhart. Improvement could be made in the height, weight and age tables.

**Vol. IX Psychology of the Child.** By David Mitchell, Ph.D. Very valuable.

**Vol. X. Educational Problems** By David Mitchell, Ph.D. Intelligence tests are evaluated.

The set is put up in a neat box, and a pair of book ends goes with each set. The title of each volume is stamped on the cover, and could be made plainer if it were colored.

The set is distinctly valuable to the mother with the growing child, and if she will follow the advice given to consult the physician, some of the peculiar advice will do no harm.

ARCHIBALD D SMITH

**AN OUTLINE OF ENDOCRINOLOGY** By W M CROFTON B.A., M.M. 12mo of 126 pages with illustrations. New York: William Wood and Company, 1925. Cloth, \$2.25

The author has succeeded in bringing together in a readable manner the most important facts in endocrinology, especially the anatomy, pathology and histology of the glands of internal secretion. The glands discussed are the pineal, pituitary, thyroid, thymus, parathyroid, suprarenal, gonads, gastro-intestinal mucosa and pancreas.

Organotherapy or the practical handling of endocrinology is not dealt with in as discriminating or critical a manner as the microscopic or chemical end. There is a tendency to accept as the last word in therapy his own personal results, especially with pluriglandular products and with pancreatic extracts which he gives by mouth and which in his opinion serve equally as well as insulin.

The term "adapter" is proposed as a generic term for all the different co-ferments produced by the pancreas. He advances the hypothesis that in diabetes the cells of the body, owing to the absence of the pancreas co-ferments, are thrown back into the condition of pre-placental days and need the food which they were obtaining then.

The book is well written and should prove of interest to those who wish a good description of the histology and pathology of the glands of internal secretion.

M B GORDON

**MEDI-CULT The A-B-C of the Medical Profession.** By B F LORANCE, M.D. Octavo of 73 pages, illustrated. Boston, Richard G Badger, 1924. Boards, \$2.50

This book is very well written. We would have wished the author had utilized his excellent style to give the reading public some larger work, choosing a greater scope for his purpose.

As it is, it will repay layman and cult-worshiper to learn, not only the "A.B.C." of the Medical Profession, but the truth about the many Cults that constantly force their way into the minds of the credulous sick and suffering. Here these Cults are shown with their camouflage removed.

The simplicity and clarity with which the subject is presented is most noteworthy.

This little book may do more to open the eyes of the outraged public than has all the venom cast upon these—Osteopaths, Chiropractors, etc., by all the Medical Societies for years.

HARRY APPEL.

**PRACTICAL ANAESTHETICS** By H EDMUND G BOYLE, OBE, M.R.C.S., L.R.C.P. and C LANGTON HEWER, MB, BS, M.R.C.S., L.R.C.P. Third Edition. London, Henry Frowde and Hodder & Stoughton, 1923. 12mo of 187 pages, illustrated. Cloth, \$2.00 (Oxford Medical Publications)

This, the third edition, is a small volume with a title which describes its content. It discusses the theory of anesthesia very little and covers quite completely the practical administration of the various anesthetics and the use of the different types of apparatus which are popular across the water.

It is interesting to learn the English point of view in anesthesia, even though it differs from ours. Boyle and Hewer appear to give chloroform the favored place in their choice of anesthetic, to judge by the fact that twenty pages of the book are devoted to it, while the discussion of ether is completed in twelve pages. Still in comparison with earlier English books on anesthesia we find that the modern methods of using nitrous oxide and ether approach more nearly what we are accustomed to in this country.

G W TONG

**LORD LISTER.** By Sir RICHMAN JOHN GODLEE, Bt KCVO, MS, FRCS. Third Edition, Revised. Oxford University Press, American Branch, New York, 1924. Price \$7.00

This edition of the biography of Lord Lister is little changed from the two preceding editions. Notes have been added in the text, and a summary of the latest methods of wound treatment is appended for comparison with those practised by Lister.

The recent death of the author, Sir Rickman J Godlee Lister's nephew, makes it unlikely that the work will undergo further revisions. It stands, therefore, as a classic in medical biography, and might well claim a place in the library of every surgeon and every medical student.

It is a fascinating story of achievement by a balanced logical mind which by persistent observation and industry reached conclusions which opened up to humanity the enormous blessings of the antiseptic treatment of wounds. It is difficult for the present day student to realize the horrors of preantiseptic days, which the nar-

## THE PROBLEM OF THE CHRONIC CARDIAC CRIPPLE— A GENERAL SURVEY \*

By JAMES B HERRICK, M.D.,  
CHICAGO ILL.

THE popular conception of heart disease, a conception shared by not a few doctors, is of an affection incurable, liable or likely to cause sudden or dropsical death, and for which practically nothing can be done. No prevention, no treatment except digitalis and rest, no prospect except an invalid's life of useless inactivity, an early, and generally a sudden death. This conception is due partly to an element of truth, partly to tradition that in passing truth from one generation to another is prone to distort facts, partly to the influence of the staggering figures showing the enormous death rate from disease of the heart and blood vessels.

It is the primary purpose of the recently organized Heart Associations, a purpose in which State and other medical societies, together with the general practitioner, will surely join, to try to improve these figures, to lessen the incidence of heart disease, and to lengthen out the life of the cardiac sufferer so that he may have a reasonable opportunity of dying the old man's death from pneumonia or at least be offered a fair chance of death in a hold up or in an automobile accident.

In the second place these associations wish to combat the erroneous that is contained in the conception to which reference has been made. They desire to educate doctors, patients and the public to a knowledge (1) that in some measure heart disease may be prevented, (2) that to a large degree an early cardiac breakdown may be forestalled, (3) that a single breakdown does not necessarily spell disaster, future invalidism and early death, (4) that knowledge of the nature of the illness with readjustment of living and working conditions may often transform the cardiac cripple from a timorous, dependent invalid into a wage-earning, self-respecting citizen.

It must be admitted that with our present imperfect knowledge of the cause of rheumatism

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, May 13 1925

and chorea and our inadequate methods of treating these diseases a large proportion of cases of acute carditis cannot be prevented. This is to be deplored for acute rheumatic carditis is the forerunner of much of the chronic cardiac invalidism. Nor can we claim very striking results in warding off the degenerative processes that accompany the marching years or the conditions that induce premature arteriosclerosis and atheromatosis with their serious cardiac effects. Yet the prevention when possible, the intelligent and thorough treatment when prevention has failed, of such infectious diseases as rheumatism, chorea, scarlet fever, diphtheria, tonsillitis and syphilis will help to prevent the development of heart complications. Preaching the gospel of moderation as opposed to that of the strenuous life with its numerous phases of speed mania may ward off many an early manifestation of high blood pressure, enlarged heart or angina pectoris.

If the objection be raised that I am speaking beside the question, as the topic assigned is not how to prevent heart disease but what to do with the individual who has it, I may fairly retort that the most logical and efficient way to treat the chronic cardiac cripple is to annihilate the disease that causes the crippling. I am not straying from the text if I stress the fact that in every way we should encourage all efforts to solve the question of rheumatism, its cause, its communicability, its early detection especially in its milder and atypical forms, the means of warding it off, and its specific treatment. Accurate scientific knowledge on these points rather than empirical guess work is the greatest need today in our contest against heart disease. May the investigations of Dr Swift and all others similarly occupied be rewarded by the results they so well deserve.

But to speak more directly of the problem of the chronic cardiac cripple.

The clinics that are under the tutelage of the Heart Associations have a serviceable classification of patients with heart disease with which

**DISEASES AND DEFORMITIES OF THE FOOT** By JOHN JOSEPH NUTT, B.L., M.D., F.A.C.S., Professor Orthopedic Surgery, Polyclinic Medical School and Hospital, Surgeon-in-Chief, New York State Orthopedic Hospital for Children. Second Edition, completely revised. E. B. Treat & Co., New York, 1925. Price, \$4.00.

The author discusses diseases and deformities of the foot, both those limited to the foot alone, and those where the foot lesion is part of a condition affecting other parts of the body.

Although the book is intended for the use of the general practitioner who has had no special training in orthopedics, we doubt very much whether the wish of the author is fulfilled, particularly as regards enabling the physician to treat foot deformities, after studying the text. We must remember that the treatment of deformities of the foot, as well as deformities of other parts of the body, requires a working knowledge of certain definite mechanical principles which require time to learn and considerable experience to apply properly.

However, we believe the book is of value in acquainting the physician with the various deformities so that he may intelligently advise the patient as to what should be done.

The section on club foot and infantile paralysis is particularly thorough and well presented.

J B L.

**PATHOLOGY AND BACTERIOLOGY OF THE EYE.** By E. TREACHER COLLINS, F.R.C.S., and M. STEPHEN MAYOU, F.R.C.S. Second Edition. Octavo, 731 pages, 306 illustrations, four colored plates. Philadelphia, P. Blakiston's Son and Co. 1925. Cloth, \$10.00.

To those of the younger generation of ophthalmologists the third edition of this work comes as a boon long needed. This is easily seen, first, because of its wide reputation handed down, and secondly, because of its peculiarly valuable text. This book approaches the subject from an angle which is very hard to find simulated in other works. Could we now have a new edition of Parson's famous work, with an appendix by Verhoeff, our minds would feel once again that our studies could be more orderly arranged.

Collins and Mayou supply a need which we can get in no other way, namely, in the vast and obscure subject of neoplasms. It seems to the reviewer that the ophthalmologists of fifteen or twenty years ago had a better and more evenly balanced library than is possible to get now from modern books, and it is to be hoped that this revision is but a beginning of the renaissance to come.

J N EVANS

**THE LIFE OF SIR WILLIAM OSLER** By HARVEY CUSHING. Two volumes. New York, Oxford University Press, 1925. Cloth, \$12.50.

*I will make a man more precious than five gold*  
—ISAIAH, xiii 12

This great work of Harvey Cushing, in two volumes, is everything a biography ought to be. The brilliant career of the extraordinary Celt (his make-up was that of the Welsh mother, not of the Anglo-Saxon father) yclept Osler who came to us and to the whole world of medicine out of his Canadian homeland, is painted so graphically upon Cushing's broad canvas that the man and his significance can be fully understood. Every incident or personage that shaped his life seems not to have been overlooked. It is the most satisfactory and the most absorbing biography that a medical man could read today.

The first volume covers the Canadian (1849-1884) and United States (1884-1905) periods, while the second one embraces the Oxford epoch (1905-1919).

This great "inseminator of other men's minds" is fortunate in his biographer, who succeeds surpassingly in portraying a rare spirit linked in some magical way with

the choicest souls of the past, he is a high priest of the pen who initiates one happily into Eleusinian mysteries, of course, the pervasive charm of the work is at bottom the charm of Osler, made to live again, it is a triumphant union of great art and a great subject.

Osler's uniqueness in his tremendous influence upon the mass of the profession even more than upon those in the forefront, which influence will increasingly affect all the medical men of posterity, is made clear in this biography. It is his fine intellect and gracious soul, shining especially out of his non-technical writings, that will rank him in the hearts of his fellow physicians, not less than his achievements for public health and for bedside teaching and its correlation with pathology as revealed in the mortuary.

The dying humanist showed his sunny nature equally with the living man of affairs. His whimsicalities and thoughtfulness concerning others even while passing slowly through the shadows of the valley was characteristic of the man. In many respects the most remarkable passages in the biography are those detailing Osler's last days.

Even the war and the loss of his son Revere at the front did not alter the humanist's traits of character and perspective, so deep-buttressed were they in sweetness and in light. Here we have the full measure of the man.

In the Westminster Abbey of medical fancy he belongs with those in the most sacred corner, under a rose-window of memory which shall be forever lit by the glow of his colleagues' affection.

A. C. JACOBSON

**X-RAY ATLAS OF NORMAL AND ABNORMAL STRUCTURES OF THE BODY** By ARCHIBALD M'KENDRICK, F.R.C.S. (Edin.), D.P.H., F.R.S.E., Surgeon-in-Charge Surgical X-ray Department, Royal Infirmary, Edinburgh, and CHARLES R. WHITTAKER, F.R.C.S. (Edin.), F.R.S.E., Assistant Lecturer Anatomy, Surgeon's Hall. William Wood & Co., New York and Edinburgh. 1925. Price, \$10.00.

This work is made up of a series of radiograms of normal and abnormal structures of the body. These radiograms are in general well reproduced. The part of this work devoted to abnormal structures includes injuries and diseases of the bones and joints, including tumors of the bone. There are also some plates of common pathological conditions found in the gastro-intestinal tract and genito-urinary system.

This work should serve as a book of reference, especially to the beginner in Roentgenology.

J G W

**LABORATORY DIAGNOSTIC METHODS. PATHOLOGICAL, BACTERIOLOGICAL, SEROLOGICAL AND CHEMICAL.** A manual for physicians, medical students and laboratory technicians. By JOHN A. KOLMER, Professor Pathology, Graduate School of Medicine, University of Pennsylvania, and FRED BOERNER, Associate in Bacteriology, Graduate School of Medicine, University of Pennsylvania. D. Appleton and Co., New York, 1925.

The value of this work is so incontestable that little need be said regarding it. In the first section the clinical pathological examinations are described fully and concisely. The subjects have been so well covered that nothing of importance has been omitted. In Section 2, is presented the bacteriological methods for examination, this is followed by a section devoted to clinical serological methods and the closing part of the volume discusses blood analysis. The various examinations are arranged in such brief yet comprehensive descriptions that the book is invaluable to the practitioner and laboratory worker who wishes a dependable working manual for time saving reference. This book should form a part of the library of every pathological laboratory.

## THE PROBLEM OF THE CHRONIC CARDIAC CRIPPLE— A GENERAL SURVEY\*

By JAMES B HERRICK, M.D.,  
CHICAGO ILL.

THE popular conception of heart disease, a conception shared by not a few doctors, is of an affection incurable, liable or likely to cause sudden or dropsical death, and for which practically nothing can be done. No prevention, no treatment except digitalis and rest, no prospect except an invalid's life of useless inactivity, an early, and generally a sudden death. This conception is due partly to an element of truth, partly to tradition that in passing truth from one generation to another is prone to distort facts, partly to the influence of the staggering figures showing the enormous death rate from disease of the heart and blood vessels.

It is the primary purpose of the recently organized Heart Associations, a purpose in which State and other medical societies, together with the general practitioner, will surely join, to try to improve these figures, to lessen the incidence of heart disease, and to lengthen out the life of the cardiac sufferer so that he may have a reasonable opportunity of dying the old man's death from pneumonia or at least be offered a fair chance of death in a hold up or in an automobile accident.

In the second place these associations wish to combat the erroneous that is contained in the conception to which reference has been made. They desire to educate doctors, patients and the public to a knowledge (1) that in some measure heart disease may be prevented, (2) that to a large degree an early cardiac breakdown may be forestalled, (3) that a single breakdown does not necessarily spell disaster, future invalidism and early death, (4) that knowledge of the nature of the illness with readjustment of living and working conditions may often transform the cardiac cripple from a timorous, dependent invalid into a wage-earning, self-respecting citizen.

It must be admitted that with our present imperfect knowledge of the cause of rheumatism

and chorea and our inadequate methods of treating these diseases a large proportion of cases of acute carditis cannot be prevented. This is to be deplored for acute rheumatic carditis is the forerunner of much of the chronic cardiac invalidism. Nor can we claim very striking results in warding off the degenerative processes that accompany the marching years or the conditions that induce premature arteriosclerosis and atheromatosis with their serious cardiac effects. Yet the prevention when possible, the intelligent and thorough treatment when prevention has failed, of such infectious diseases as rheumatism, chorea, scarlet fever, diphtheria, tonsillitis and syphilis will help to prevent the development of heart complications. Preaching the gospel of moderation as opposed to that of the strenuous life with its numerous phases of speed mania may ward off many an early manifestation of high blood pressure, enlarged heart or angina pectoris.

If the objection be raised that I am speaking beside the question, as the topic assigned is not how to prevent heart disease but what to do with the individual who has it, I may fairly retort that the most logical and efficient way to treat the chronic cardiac cripple is to annihilate the disease that causes the crippling. I am not straying from the text if I stress the fact that in every way we should encourage all efforts to solve the question of rheumatism, its cause, its communicability, its early detection especially in its milder and atypical forms, the means of warding it off, and its specific treatment. Accurate scientific knowledge on these points rather than empirical guess work is the greatest need today in our contest against heart disease. May the investigations of Dr Swift and all others similarly occupied be rewarded by the results they so well deserve.

But to speak more directly of the problem of the chronic cardiac cripple.

The clinics that are under the tutelage of the Heart Associations have a serviceable classification of patients with heart disease with which

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse, May 13 1925

you are probably familiar. It is based on the capacity of the heart to perform its function. They have a class in which the heart shows no disability, another with slight disability, another with marked disability, etc.

For my purpose this afternoon I wish to modify the classification a little and to make five groups of patients with heart disease: 1. the chronic cardiac cripples. It is not intended to supplant the other, it would not answer the purposes of the clinic, but it may help to get before us in a little clearer light some of the salient features of the problem.

The five groups of cardiac cripples are as follows:

1 Patients who have no heart disease but think they have.

2 Patients who have heart disease but think they have not, at least they are ignorant of the fact.

3 Patients who have heart disease, who know it, who think they are incapacitated for all work and doomed to early death, but who are mistaken in their belief.

4 Patients who have heart disease but refuse, or are unable, to act on proper advice as to its management.

5 Patients who have heart disease, know it, are willing and able to accept, and to act in accordance with, advice as to its proper management.

May I call attention a little more in detail to some of the features of these five groups?

*Group 1* The patient has no heart disease but thinks he has.

In all the cardiac clinics the percentage of referred and visiting patients found on examination to be non-cardiac is large. Yet they have come to the doctor in the clinic just as others go to the specialist or to the family doctor because they—or perhaps the anxious parent—think they have some affection of the heart. A little palpitation or a spell of breathlessness, fatigue and anxiety from watching the last hours of a mother's cardiac breakdown, the news of the sudden anginal death of a friend, reading or gossip concerning the symptoms and dangers of heart disease may be sufficient to arouse fear and even to start mimicry in the one who is susceptible and neurotic. And often it is the doctor who thoughtlessly though in innocence, lets fall the hint as to low blood pressure, weak or rapid heart action, a faint murmur or lack of perfect rhythm, together with a word of caution as to over-exertion, which hint arouses in the impressionable individual a dread of the disease that is sometimes almost as bad as the disease itself. I am not including in this list the so-called irritable heart, an innocent extrasystole, certain types of tachycardia, or sinus arrhythmia, for while these are generally not serious they are definitely

cardiac in their manifestations and must be so classed.

It is in this type of case that the trusted family doctor, the wise specialist or the patient dispensary physician can by thorough examination, frank explanation, tactful suggestion and encouragement give reassurance and hope to one who is often sorely and genuinely distressed because of worry over the fancied disease.

*Group 2* The patient has heart disease but does not know it. He comes in for symptoms not recognized by him as cardiac. Perhaps the lesion is discovered in a routine health examination or accidentally during some acute illness or accident. Here is the opportunity to inform and to educate so as to prevent an early breakdown. He must be guarded against the danger of doing that which is liable to harm him. It may be unnecessary to tell the patient, perhaps only the parents need know. The blunt assertion that heart disease exists, that activity must be restricted may cause anything but favorable results. The utmost tact is required. There are honest, helpful yet gentle ways of telling a man he has even angina pectoris.

*Group 3* The patient has heart disease but is overfearful concerning it and especially is apprehensive regarding exercise. The anxious mother forbids the child to play, the adult feels that he takes his life in his hand if he walks up a flight of steps.

Instruction is needed here. It may be necessary to emphasize that not only may some hearts endure the strain of moderate exercise but some hearts need such exercise. Many individuals should be told that from the cardiac standpoint they may, can, and must work.

Two years ago a group of young women in Chicago opened a summer camp for a few weeks to cardiac children, *Group A*. These women were astonished to be told that the third floor of the building would be available, that the children would easily manage the stairs. They were relieved of anxiety when at the end of the season they found that all the children had gone through the summer not only unharmed by the stairs but benefitted by the outing and they admitted that they had learned much as to the capacity for exercise of a damaged heart.

*Group 4* The patient has heart disease but will not or cannot act on the advice given. He may decline through ignorance, or through obsession as to the value of certain cults, or the stress of poverty or the urge of riches may make him feel unable to do as he is told. All that the doctor or the clinic can do here is to advise, persuade or perhaps put the patient in touch with agencies that will make it possible for him to carry out the physician's directions.

*Group 5* The patient has heart disease, knows

What to do for these five groups? How to do it? How to get the first four groups into the last group where the patient is amenable to treatment? It is a big problem, involving many contacts—the patient, the home, the school, the workshop, the office, the employer, the compensation board, the employee, the union, the public health department, the family doctor, the clinic, the dispensary, the hospital, the convalescent home, the social service department, the vocational guidance organizations and many others, contacts that are medical, humanitarian, social, economic

The task though formidable is not impossible. It involves chiefly two things, first, the finding of the patients and then the education of doctors, patients and the public as to the proper management of these cases

Surveys of schools, examination of workmen, spread of the doctrine of periodic health examinations, attention to this matter on the part of family doctors will result in a disclosure of the cardiac cripples

In the matter of education we should begin with ourselves. Few of us are as wide awake as we should be to the magnitude of this question, to its importance and to the possibilities of good that may result. As has been said we need more accurate knowledge as to the cause of rheumatism and arteriosclerosis. Clinical and laboratory research should be encouraged. We should have more definite knowledge as to the communicability of rheumatism, chorea, tonsillitis and some of the purpuras. The lesson should be hammered home that the prevention of syphilis and its early intensive treatment will lessen the number of cases of heart disease in young adults and those older. Gonorrhoea, tonsillitis, scarlet fever should be viewed as dangerous from the standpoint of possible acute or chronic carditis. Prolonged rest in rheumatic carditis should be more generally practiced. Many physicians need elementary schooling in physical diagnosis of the heart, not so much that they may be able to detect a change in size, an altered rate or rhythm or an adventitious sound as that they may interpret such finding sanely and not extravagantly.

And how much there is in the way of education of the patient—the home life, the type of exercise, the appropriate diet, the school, occupation, marriage, childbearing. These features will, I am sure, be brought out by others and need not be here dwelt upon.

Hospitals, dispensaries, clinics need education. Too often the hospital in its desire for rapid turn over discharges the patient with a cardiac breakdown too early. It should be shown the error of such an act. The dispensary and the cardiac clinic, the latter the connecting link between the patient and his home, the workshop and the hospital, should be made to realize—I think most of them do realize—the opportunity they have for studying these cases as individuals, for treat-

ing them by advice and drugs, and through the indispensable social service department seeing that the patient lives as directed.

The public must be made to see that the heart problem is not simply one of how best to care for a hopeless invalid, not simply one of charity and kindheartedness. It must be made to see as well its sociologic and utilitarian aspects. The man with heart disease may be 25, 50 or 75 per cent efficient as a worker and wage earner. With work suited to his physical condition he may make good up to 100 per cent. He need not necessarily be an object of charity for whose support the community is taxed, he may himself become a taxpayer or a taxdodger. He may be converted from a liability into an asset. It was estimated that in one year in a small cardiac clinic in Chicago \$26,000 had been earned by patients who without the instruction as to the nature of their illness, the proper use of drugs, etc., would have earned nothing, but would have been dependent on others for support.

All this implies education and what is commonly called propaganda. Interest must be aroused and maintained. The clinic is the informing focus from which productive information is to emanate, because instruction is here not alone didactic, it is practical. One case thoroughly studied by doctor and social worker in its medical and social aspects, followed up at home, school and factory is worth more from the missionary point of view than gospel tidings proclaimed in a lecture or pamphlet. The concrete example of the case benefitted is the best kind of advertisement of the cause.

Still, the more fortunate class of people, those higher in the social scale, will be more effectively reached at first at least, by means of talks, lectures, newspaper and magazine articles and bulletins. We have had in Chicago a very useful help in our Heart Association Bulletin published at frequent intervals. The Health Department has asked us to get out one number of its monthly bulletin.

The Chicago Heart Association was asked if it would not for publication in the *Journal of the Manufacturer's Association* answer the question why today so many prominent men were dying of heart disease. One of our members saw his opportunity and in his reply informed the editor that men of wealth and prominent had no monopoly on heart disease, the poor and the middle class were also afflicted. He invited the co-operation of these men of wealth and influence in trying to find out how the tragedies and fatalities of heart disease, among rich and poor, might be lessened.

The influence of the Heart number of *The Survey* has been, I am sure, widespread and helpful.

I fear I have yielded to the temptation offered

by the very broad topic assigned me—a general survey of the problem—to speak rather vaguely and in discursive manner. If I sum up the few points I have tried to make it would read somewhat as follows:

The problem is to correct erroneous notions concerning heart disease and erroneous practice, it is to arouse public interest and to see that this interest is intelligent because enlightened by the spread of accurate and scientific information, to foster laboratory and bedside research, to back up the efforts of the general practitioner, the specialist, and particularly the doctor in the clinic and the social worker, all those who come into

close personal contact with the patient, recognizing that these represent the backbone, the brain and cord of the movement without which it will collapse and its efforts be incoordinate and fruitless, to encourage the convalescent home, to assist in occupational training and occupational placement.

In short it is, so far as possible, to prevent the disease, to prevent the early breakdown, to prevent the consigning of the cardiac cripple to the junk heap. When, and if, all these efforts fail, to see that the days of the final breakdown are made as happy and free from suffering as possible.

## STATISTICAL ASPECTS OF THE PROBLEM OF ORGANIC HEART DISEASE\*

By LOUIS I DUBLIN, Ph.D.,

NEW YORK CITY

**H**EART disease in its various manifestations is first in the order of causes of death and, I am inclined to think, the first also in the amount of damage it does through disability and invalidism. The evidence for mortality is much more complete and decisive so that I shall give that first. The annual quota of deaths in the United States is now close to 200,000. If present conditions continue, one in every five of the population living at age of 10 will eventually succumb to organic heart disease. The child at ten years of age is now three times as likely to die eventually from heart disease as from tuberculosis. At age 35, the probability of dying eventually from heart disease is, among males, nearly four times that for tuberculosis and, among females, the probability is almost six times that for tuberculosis. A revolutionary change has taken place in the general mortality picture during the last twenty-five years coincident with the development of preventive medicine and the public health movement.

It is also very likely that the pre-eminence of heart disease as a cause of death will increase rather than decrease as time progresses. The gradual improvement in the death rate for such diseases as tuberculosis, pneumonia, and others that are coming under control, will transfer many additional persons to the later ages in life when heart disease is likely to strike them down. Under conditions of twenty or thirty years ago, many of them would have died in early life from the conditions referred to, today, they survive to middle life only to become victims of heart disease, cancer, apoplexy, or Bright's disease. This is an item which must not be lost sight of,

especially in view of the fact that the medical profession is not so well organized to control heart disease as it has been for twenty years organized to combat tuberculosis. It is for this reason that I consider heart disease the outstanding problem in contemporary preventive medicine. Nothing within the province of the physician today compares with it. I have in another place estimated that if heart disease could be eradicated as a cause of death, every one in the population would have about two years added to his expectation of life—not a small matter when the economic value of a year of life is considered.

The first question I would like to take up with you is whether the mortality from heart disease is beginning to show any signs of improvement. Between 1910 and 1918, the indications were that the mortality rate was rising slightly. The years 1917 and 1918 showed the maximum death rates of this period. The three following years, 1919, 1920, and 1921, were years of low rates, and there is every indication that this was largely due to the elimination of many persons through the influenza in 1918 who would ordinarily have died of heart disease in subsequent years. Beginning with 1922, the trend has been slightly upward, and there is really no saying what the picture in the immediate future will be like. In the first four months of 1925, the experience among the sixteen million Industrial policyholders of the Metropolitan, which is usually very sensitive as an index of what will be found later in the general population, showed an increase of four per cent over the same months of the year before. The facts for the fourteen years beginning with 1911 are shown in the following table.

\*Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 13, 1925.

TABLE 1

Death rates per 100,000 for Organic Diseases of Heart. Experience of Metropolitan Life Insurance Company, Industrial Department (Ages one and over) and Expanding U S Registration Area (All ages)

Year	Metropolitan Life Industrial Dept. Ages one and over	Expanding U S Registration Area (All ages)
1924	125.5	*
1923	128.7	157.3
1922	126.7	148.4
1921	117.4	140.9
1920	117.0	141.9
1919	113.9	131.0
1918	141.7	153.3
1917	142.0	153.8
1916	140.2	150.6
1915	136.7	147.6
1914	138.1	142.2
1913	140.6	138.9
1912	143.8	142.8
1911	141.8	141.1

\* Not available.

monia combined. After forty, the rate of mortality rises precipitously, and the priority of heart conditions is then unquestioned. But it should not be forgotten that these deaths of middle-aged men and women, in most instances, involve a loss of many years of productive life to which they would ordinarily have been entitled, and often of years of diminished efficiency and even of complete invalidism prior to death. Deaths at these ages also produce in many cases broken families, widows, and orphaned children thrown upon the community for support. The curve of mortality from heart disease by age is a very interesting one, and I present one herewith in contrast with the curve for tuberculosis. The latter disease now shows its maximum at or about twenty-five years of age and then declines with advancing years. But heart disease crosses the tuberculosis curve about the age of forty-five and then mounts to its huge maxi-

Heart disease is pre-eminently a condition of the older ages of life, but, it is by no means to be neglected as a cause of death in the early years. In 1924, for example, the Metropolitan Life Insurance Company recorded close to twenty thousand deaths from heart disease among its Industrial policyholders. Of this number, 1,600, or eight per cent were of persons under the age of twenty-five, and 3,400, or 17 per cent, were under the age of forty. In other words, one-sixth of the insured who died from heart disease were at their prime. At the younger ages of adult life, heart disease is responsible for as many deaths as are all forms of pneu-

monia at the oldest ages. The principal damage to the community has, however, been accomplished long before old age is reached. Sixty-eight per cent of all heart disease deaths, in the experience of the Metropolitan Life Insurance Company, occur before the age of sixty-five.

Among white persons, the death rates are very much the same for the two sexes up to the age of twenty-five. After the age of twenty-five, the death rate for white males is higher than for females and the excess between the sexes becomes greater with advancing age. The rate among colored people is at every age higher than for whites. In fact, during the main age

periods of life, the rates for colored people are about twice that for whites at the corresponding ages. It is also noteworthy that at some ages in adult life, the rates for colored females are higher than for colored males. It has been suggested that the higher prevalence of such diseases as malaria, typhoid fever and especially syphilis in the colored race, plays an important part in creating this excess of heart disease among them. But possibly, also, the figures presented are not all that they ought to be, because of the great difficulty in obtaining reliable statements of the causes of death on certificates. We shall always be troubled with our figures for heart disease until there are a larger number of autopsies and the standards of medical practice are generally raised.

TABLE 2

Death Rates per 100,000 for Organic Diseases of the Heart. Metropolitan Life Insurance Company, Industrial Department, 1923

Age period	White		Colored	
	Males	Females	Males	Females
All ages—one and over	113.6	122.1	190.8	217.4
1 to 4	6.3	6.2	17.1	10.3
5 to 9	10.3	10.8	17.5	10.8
10 to 14	19.8	23.2	28.9	16.0
15 to 19	27.6	23.9	28.4	19.3
20 to 24	23.9	25.2	27.6	38.1
25 to 34	39.6	32.4	68.0	58.7
35 to 44	86.6	70.7	180.3	184.7
45 to 54	253.3	184.9	424.6	470.4
55 to 64	681.3	535.6	831.9	948.8
65 to 74	1719.9	1545.4	1595.6	1641.1
75 and over	4060.8	3524.7	2600.1	3016.5

I have touched on the principal points in the mortality picture. I wish I could speak with as much assurance on the morbidity aspect of our subject. Unfortunately, that is impossible in the present state of our knowledge. We have made only the merest beginnings in collecting information on the incidence of heart disease in the community. Our very definitions are still vague. I should not have been able to make a presentation today if I had been kept to a literal interpretation of the title of this symposium. For, what is really a cardiac cripple? When does the condition justify such a designation in that shadow zone between the functional and organic heart case? Primarily, the difficulty lies in the fact that organic heart impairments ordinarily are not discovered in the early stages, and even then, there is no provision for systematic records of the after-history of the cases. This most valuable information, therefore, lies hidden away either in the memories of the one hundred thousand or more practicing physicians, or in their uncompiled and unanalyzed records. It is only recently that we have made a beginning, through the work of the cardiac clinics, to gather such information as we need on the morbidity of heart disease. It will always be a source of satisfaction to me to have had an opportunity to co-operate with Dr. Alfred Cohn in the preparation of the record forms used in these clinics. It is, indeed, fortunate that today we are able to tap this source of information from the unpublished work of Dr. Wyckoff, who has com-

piled and analyzed the records of a thousand patients in his service. These data are probably the only ones available at the present time, and I wish to acknowledge my great indebtedness to Dr Wyckoff and his associates who placed this material at my disposal for this occasion

In a previous paper, I have indicated that the number of persons suffering from definite organic heart disease approximated two per cent of the total population. This is a rough estimate. It is suggested by the findings of the life insurance companies in their routine examination of applicants for insurance, by the findings of the Life Extension Institute in their examinations, and by the results of others who have made physical examinations of large numbers of school children, employees in shops and factories and of other groups. This figure should, of course, be considered only a first approximation and will give place to a more definite one as further work is done on the records. It will serve, however, as our starting point. On this basis, there are well in advance of two million men, women, and children with organic heart lesions, and if the number of deaths annually from this group of diseases is in effect 200,000, we may infer that the average duration of a case of heart disease is about ten years. This will, of course, vary with the age at which the lesion occurs, with the type of lesion, the care which the individual receives and a host of other factors which bear on the condition. But, this figure of average duration will serve as a beginning to guide our discussion.

What are some of the outstanding findings in the tabulations of Dr Wyckoff? The thousand cases were distributed etiologically as follows: About one-fourth presented rheumatic heart disease, about two-fifths, arterio-sclerotic, about one-tenth, syphilitic, and about another one-tenth, heart disease of unknown origin. The remaining 15 per cent are accounted for by a mixture of odds and ends which are not so easily classified. The cases of rheumatic and unknown etiology are discovered, for the most part, at the earlier ages, the cases of arterio sclerotic etiology appear in the later age groups. The great presumptive importance of rheumatic fever as a causative factor is clearly indicated by the findings of Dr Wyckoff and his associates. It would be very interesting to find out what the relative duration of these cases of rheumatic origin is in contrast with the duration of cases of degenerative heart disease. The seriousness of syphilis as a primary causative agent is no surprise. Probably, the figure of ten per cent is a minimal value in view of the difficulty of determining in every instance the presence of the spirochete and the incompleteness of case histories. It is important, however, to observe that this type of heart disease is most prominent in the fifth and sixth decades of life. It is especially among the colored patients

that syphilitic heart disease is prominent, in this group, it accounts for about a third of the cases.

An equally valuable classification prepared by Dr Wyckoff and his associates is that showing the incidence of structural lesions in these 1,000 cases of organic heart disease. They found 88 per cent of the cases showing enlargements of the heart, among whom one in five had enlargement of the heart only. Hypertrophy was, by all odds, the commonest impairment. Mitral insufficiency was diagnosed in approximately half of all the cases. Mitral stenosis was present in 44 per cent of the cases, but, in nearly all of these, mitral regurgitation was also present. Aortic insufficiency was present in about 15 per cent of the cases, aortic stenosis in about three per cent, aortitis in 17 per cent, and aneurism in a little over one per cent. The following table is taken from Dr Wyckoff's report, with his permission.

TABLE 3  
Incidence of Structural Lesions in 1,000 Cases of Organic Heart Disease.

Structural Lesion	Males		Females		Both Sexes	
	No.	Per cent	No.	Per cent	No.	Per cent
Enlargement of Heart	342	54.2	341	34.1	684	88.4
Enlargement of Heart, only	137	13.7	66	6.6	203	20.3
Mitral Insufficiency	228	22.8	267	26.7	495	49.5
Mitral Stenosis	210	21.6	227	22.7	443	44.3
Aortic Insufficiency	178	17.8	68	6.8	146	14.6
Aortic Stenosis	23	2.3	6	.6	29	2.9
Aortitis	142	14.2	27	2.7	169	16.9
Aneurism	11	1.1	1	.1	12	1.2
Mitral Insufficiency and Stenosis	202	20.2	219	21.9	421	42.1
Mitral Insufficiency and Stenosis and Aortic Insufficiency	82	8.2	40	4.0	162	16.2
Mitral Insufficiency and Stenosis and Aortic Insufficiency and Sten	6	.6	6	.6	12	1.2

This report when it is published should receive the careful attention of all physicians as it is, in fact, the first attempt, to my knowledge, to collect a large body of information of an authen-

tic character in this field of heart disease prevalence. We have, heretofore, had any number of sketchy and loose statements of diagnostic findings. But, this series stands by itself in the authority of the examiners and the fullness of the records. This report should stimulate others in the field to collect similar case records and to tabulate and analyze them along comparable lines. A very great service could be rendered to this branch of medicine by spreading the use of these forms not only in clinics, but also among physicians in private practice.

I wish now to turn to a third source of information on the prevalence and significance of the heart diseases, namely, the records of the life insurance companies. A number of the larger companies have been for years liberal in their acceptance of certain types of heart cases for sub-standard insurance. The examinations for insurance are, of course, not made with that same thoroughness which characterizes the work of the cardiac clinics. But, the insurance applications do, nevertheless, make possible the classification of the heart findings of large numbers of people with a fair degree of accuracy. The heart defect most frequently found is mitral regurgitation. Hypertrophy of the heart without other heart signs is next in importance. Mitral stenosis, aortic stenosis and aortic insufficiency follow in order of frequency. This order is very much like that of Dr. Wyckoff's material, but, I doubt very much whether the examinations as conducted by insurance medical examiners in the field are of sufficient accuracy and refinement to find all the cases with heart lesions or to diagnose them correctly. Yet, the parallelism is very interesting. The medical directors of the life insurance companies are confronted with the practical problem of evaluating these lives and placing them in the several risk classes for which mortality rates and premiums have been computed. When insurance is granted, an excellent opportunity is afforded to the medical director of following the subsequent mortality experience on such persons.

A number of companies have, in this manner, collected considerable data on the after mortality of cases with mitral regurgitation which, I believe, will interest you. The experience covers a period of close to twenty-five years and is based on many thousands of persons. Taken altogether, the mortality rate is about two and a half times as high as that which prevails among normal persons accepted for standard insurance, age period being considered. Those cases where the murmur is slight but not transmitted have only a slight excess over normal mortality. The

presence of a well marked hypertrophy adds to the hazard, as does also the history of rheumatic fever or other acute inflammatory processes. You will all remember Dr. Mackenzie's very favorable prognosis of these cases. He felt that the insurance companies were losing a great deal of good business in not accepting these cases. But, our experience has shown, I am afraid, that his impressions were not correct, although it may well be that these cases of mitral insufficiency constitute the least impaired of the organic heart cases. In this connection, it is interesting to note that close to half of the deaths which occurred among the mitral insufficiency cases were from organic heart disease of one form or another. Cases of aortic stenosis and of intermittent heart disease gave an experience very much like that from mitral insufficiency, i.e., double mortality. In a few instances, the insurance companies have accepted risks affected with mitral stenosis, but the experience is uniformly bad, and the present practice is to reject such cases. The available insurance experience is, however, insufficient to give reliable results on the precise effect on longevity of these very serious impairments.

I have mentioned the practice of the insurance companies in this connection with a special point in mind. The medical directors of the insurance companies are keenly interested in the work of your clinics. As physicians they are, of course, very much concerned with the prevention of suffering and the postponement of death. But, as insurance men, they are also concerned with providing an equitable classification of the risks presented to their respective companies. They are all of them very anxious to provide protection for the families of persons affected with impairments, but, it is always necessary that such insurance protection be granted with no unfairness to those who are already insured. For this reason, the medical directors have been compelled to proceed cautiously with the acceptance of risks showing heart impairments. It is quite possible that the new movement for the study of heart disease will provide the very information which will make it possible for the companies to extend their operations to such cases and to offer insurance to lives which are not now accepted because of the dearth of information on the after mortality of such risks. There are large opportunities for co-operation between your heart clinics on the one hand, and the insurance companies on the other. I believe it would be a very profitable procedure for both groups to get closer together if for no more than to explore the opportunities for further research.

## A PROGRAM OF PROCEDURE IN THE PROBLEM OF THE CARDIAC CRIPPLE\*

By HOMER F SWIFT, M.D.,

NEW YORK CITY

**D**URING the past winter a committee of the New York Heart Association has been making a general survey of the special work among cardiac patients, and trying to devise plans for future work with these patients. At the meetings of this committee persons in the field of public health, and vital statistics, as well as those more specially concerned with the various phases of heart disease were consulted. The following observations and suggestions were derived in large part from the deliberations of this committee. They represent, therefore, not the opinions of one individual, but the ideas of many.

Statistical data concerning heart disease, or rather "heart diseases" compared with the falling death rates from most infections render it difficult to claim that much has been accomplished up to the present in diminishing the mortality from heart disease. This discouraging evidence immediately requires us to examine the reasons for the apparent lack of beneficial results from all of the efforts that have thus far been expended. Certain questions may be asked. Are the sources of our information reliable? Is it possible to analyze them in such a manner that they will give us some approximation of the truth? If not, what measures may be proposed in order to remedy these defects in our present sources of knowledge? Is it possible with our existing machinery to obtain reliable information, or must new methods be devised and adopted in order eventually to have more dependable guides to the efficacy of our prophylactic and therapeutic procedures?

The complicated nature of heart disease and the multiplicity of conditions covered by the term confuse the picture. For example, all vital statistics indicate that "organic diseases of the heart" is the largest single cause of death, and that the rate is apparently increasing from year to year. But "organic disease of the heart" is an all embracing term. Death rates from most infectious diseases have fallen steadily in the past few decades with the result that expectancy tables show the span of life to have been definitely lengthened, hence increased death rate from degenerative types of cardiac vascular disease is to be expected. In this group we are faced with the apparently paradoxical statement that both personal and general health measures calculated to prevent a disease may in the end lead to an increased statistical death rate from that disease. It is a question, therefore, whether this portion of

the problem, i.e., degenerative heart disease, does not belong in its broader aspects to the general field of public health, and in its narrower implications to the physiology and pathology of senescence.

The first requirement in any plan of procedure then, is the adoption of some simple form of classification of heart disease. Naturally the type of classification adopted differs according to the use to which it is to be applied. Thus the New York Heart Association is using a system in which the functional state of the organ is the primary consideration. This has proven most useful from the standpoint of treatment of the crippled heart. Provided the criteria of functional classification are correct, it enables physicians to adopt therapeutic measures which are directed towards moving the patient into a more favorable functional position. Obviously most cardiac cripples have irreparable heart failure just prior to death, hence from the viewpoint of vital statistics as well as from that of preventive medicine a functional classification is of relatively little value. If seems, therefore, advisable to adopt an etiologic system. Even with the evident difficulties of assigning a definite etiologic agent to all cases of heart disease, and with the probability of often encountering differences of opinion as to the relative importance of a number of different causative factors, it is still of value from practically every angle to attempt to determine the origin of the disease, or condition leading to the diminished functional state of the heart, and also to designate whether that disease is active, recurring, quiescent, or cured.

On this basis, the following classification of Heart Disease has been suggested

- I Infectious
  - a Rheumatic Fever
  - b Syphilis
  - c Other infections (type to be stated)
- II Degenerative and senescent.
- III Concomitant state in—
  - a Chronic Bright's disease
  - b Arterial hypertension
- IV Fatigue—Toxic states
- V Neurosis—so-called Functional Heart Disease.

In order to operate successfully the natural history of each of these forms of heart disease must be known, and the differences between them clearly emphasized. Information in respect to one is not equivalent to information in all. For example, we have sufficient knowledge of syphilis and enough methods of diagnosis and treatment to eradicate it, if all of the means at our disposal could be effectively utilized. It is safe to

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 13 1925

predict then, that syphilis of the heart will be eventually eliminated through the thorough application of information already available. In respect to rheumatic fever, on the other hand, we have much to learn before we can begin to apply effective prophylactic measures. It may be useful to quote the remarks of a well known cardiologist concerning our lack of knowledge: "We do not know the cause of rheumatic fever and chorea, or the communicability of these diseases, the relationship of focal infections (tonsils, teeth, lymph glands, and intestinal tract) to rheumatic fever, the therapeutic value of the removal of these foci, the natural history of a large group of these patients followed over long periods of time, methods for preventing rheumatic fever, the best methods for handling these patients at various stages of their disease." The controversial nature of our knowledge of nephritis and hypertensive cardio-renal disease does not require special emphasis. This agnostic attitude is not necessarily pessimistic, nor does it prevent efforts at solution. On the contrary, honest recognition of deficiency in knowledge is the first step towards remedying our shortcomings. Numerous groups of workers are engaged in attempting to solve many of these problems. It goes without saying that every encouragement should be given to all these efforts, for more than one example might be cited in which the work of a single individual or small group furnished the method by which the larger problem was successfully solved.

In the meantime there are many lines in which co-operative effort would probably prove beneficial. Mention has already been made of the difficulty of obtaining much useful information from vital statistics because they reflect only unclassified mortality rates. More might be expected from morbidity returns. In this respect, although heart disease is recognized as the largest single cause of death, when we compare the lack of requirements of Boards of Health for physicians to furnish information in reference to its incidence with their efforts to record cases of diarrheas of infancy, dysentery, or chickenpox, our first impulse is one of surprise. If cardiac disease were made reportable on forms following well defined etiologic classification so that the relation of various predisposing factors to the actual circulatory disease could be determined, it is conceivable that after a number of years a mass of very useful information might be secured and the trend of the results of our therapeutic efforts might be determined. But the objection is raised that no immediate benefit could be expected from this information and that without this immediate benefit in sight, health authorities are loath to make demands for reports from practitioners, and are adverse to enlarge the Board of Health statistical departments. Our inability, therefore, to apply some

prophylactic measures as an immediate result of these reports prevents us, as physicians especially interested in cardiac disease, from urging the adoption of measures which would probably yield information of decided value in the future.

More limited groups of individuals from which morbidity figures may be obtained are insured persons, conscripts and school children. Statistics of insured workers, while of value, cover only a small group of cardiacs, for most patients with cardiac disease are, of necessity, excluded from the benefits of insurance. Morbidity curves and expectancy tables based on statistics of life insurance companies are, therefore, not applicable to the majority of cardiac patients. Morbidity rates among conscripts give us merely a single cross section in a limited group of the total population, they do not cover the early and late periods of life when cardiac disease is an important public health problem. Morbidity studies in school children permit of a slightly larger range in that the patients might be followed over a longer period, and are under certain control. Education is, however, the primary object of the schools, and although much is being done to improve the general health of school children the results of these efforts, in respect to heart disease, will not be made known unless there is a definite plan to correlate corrective and therapeutic efforts with a study of what follows their application. It must not be forgotten that the better nutritional states and housing conditions existing today in America, apart from any special prophylactic or therapeutic measures, may have much to do with improving the health of school children.

It is evident that there is no unanimity as to the best methods of treating cardiac school children. If they are considered from the standpoint of functional classification, treatment directed mainly towards lightening the burden of a crippled heart might be recommended. If, on the other hand, the child with heart disease is considered as having reacted in a peculiar manner to certain infections and as being a subject especially susceptible to reinfection, or to the re-awakening of latent infection, it seems probable that he would best be treated in a manner especially calculated to keep his resistance against infection at the highest possible level, as well as to guard against straining his crippled heart. The answer to the question as to the best course of treatment of cardiac school children cannot be reached by a single survey of these children, but requires the repeated observation over many years of different groups of patients from various social levels, treated in various ways. Hence, there should be added to the existing work on the study of cardiac disease in school children a definite plan for obtaining information on these points.

In smaller cities with a comparatively fixed

population and few schools this type of continuous investigation could be most advantageously pursued. The need for information along these lines is emphasized when we realize that, among school children, heart disease, chiefly rheumatic in nature, is the cause of three times as many deaths as pulmonary tuberculosis.

The Milbank Foundation is, at present, preparing to investigate the general public health problem in a relatively large district in New York City and in Syracuse, and of necessity heart disease must occupy a considerable portion of the programs. In this work the Milbank Directors and Heart Associations might be mutually helpful, for the former have the funds and the desire to obtain information that may be used in forming programs for future work and the latter has, through its Research Committee, a well considered plan as to how observations in reference to heart disease should be made and recorded. Already the records of many cardiac patients in the Bellevue-Yorkville district are documented on the Heart Association charts, and with these as a model nucleus, the Milbank cardiac investigations may be made to proceed much more rapidly than if the Milbank directors try to originate their own methods and forms. The cardiac clinics situated in the district should be urged to assist in this work, in order to demonstrate the mutual advantages of co-operation.

Studies among any special group are of necessity limited, either because of the restricted life of the investigating committee, or because the individuals under observation pass beyond the jurisdiction of the investigators. The picture obtained, although accurate, is more or less limited. Even were the supervision of cardiac school children perfectly organized our knowledge of the ultimate result of this special care would be largely lost unless plans were perfected for following them in the post school period.

A study of the various factors which are favorable, or unfavorable, to a patient with heart disease must be pursued for many years and must be made in all the places where the patient is found, viz, in his home and place of work, in the wards, the out-patient cardiac clinic and convalescent homes, and in the consulting rooms and bedside with private patients. The observations, moreover, should be made by physicians and social workers, who are specially trained in the interpretation of the signs and symptoms of heart disease and in the detection of unfavorable and favorable environmental influences. Indeed, hundreds of patients are observed daily in the various institutions of this country but the results of the observations are only of benefit, directly to the patient, and indirectly to the physicians, or group of physicians, having to do immediately with the patient. Our present state of uncertainty in respect to the solution of many practical problems is not that these have not been

considered, or worked upon, but rather in the failure to make known the results of the work already done. Again, each physician, or group of physicians, in an institution works in a more or less individual way, with but little consideration of how the observations are made or recorded elsewhere. The records of cardiac patients in a hospital, or clinic in many instances must correspond in size and form with the records of other classes of patients in that institution, rather than with the notes of cardiac patients in another institution. This has resulted in different groups of workers being less mutually helpful than would be possible under better circumstances. There is little common plan of procedure and hence, little common language. What Group A may do cannot be interpreted in terms of what Group B has done, because the two cannot compare directly their observations and results. How many more divergent points of view arise when the number of groups is increased by twenty to forty is obvious.

Another reason for our incomplete knowledge of the life history of cardiac disease is that at various times the cardiac patient is under different observers, in the wards of hospitals, in the out-patient cardiac clinic, in the convalescent home, and often under the care of a private physician. As a rule the observers in each unit have relatively little accurate knowledge of what has occurred to the patient while he was under the care of physicians in other institutions, or even in other parts of the same institution. In hospitals, employing a unit history in wards and out-patient department, the gap is bridged to a certain extent, but the convalescent home is practically always out of documentary touch with wards and out-patient clinics, and at best a functional classification is attached to the transfer cards as a patient moves from one observer to another.

For economic and administrative reasons, it seems necessary to divide the patients into classes according to the present scheme. It is conceivable that a special cardiac hospital, or cardiac unit, in a general hospital might be so arranged that the patients, no matter in what condition from acute illness through convalescence, were under one group of observers constantly and that from such a cardiac unit, much useful information would arise. Some cardiac clinics are at present so organized that the patients are under the direction of the same physician both in the wards and out-patient departments. It is easy to imagine the expansion of this type of work so that a special cardiac hospital were so staffed that the patients could be observed, treated and specially trained, all at the same time. In fact, model institutions of this general type have been most valuable in pointing the way to the best form of treatment of tuberculosis.

Today, however, we must face existing condi-

tions and make the best use of them. About seven thousand patients per year are now under the care of various groups of physicians in 48 different cardiac clinics in New York City. There is already a certain degree of co-ordination between many of these groups in that meetings are held and opinions and experiences interchanged, but it may be asked whether, with the present plan of procedure, we shall, at the end of five or ten years, have made much progress in the solution of any phase of the cardiac problem. A regrettable feature of the whole situation is that with the present lack of mutual co-operation, we shall be unable to determine either our rate of progress, or lack of progress, if such exists.

Heart Associations or physicians in other cities of the state might conceivably be able to co-operate more effectively than do those of the metropolis, for the size of the problem among millions of people makes organization complex and cumbersome. To the worker in smaller places we may recall that Trudeau did more than any metropolitan physician to point the way to proper treatment of tuberculosis, and Sir James MacKenzie, after experience both in the country and in London, selected St Andrews as a more favorable place to study the life history of chronic cardiac disease than he found in a London hospital. The recent work of Kaiser in following a large group of tonsillectomized children and comparing them with a similar group of unoperated ones, shows how a study of clinical material may help us form an opinion of certain prophylactic measures.

At this point we may digress a moment to indicate some benefits to be obtained from the study of the relation of tonsillectomy to rheumatic fever and cardiac disease. It may be that eventually among a group of tonsillectomized individuals there will be as large a proportion having rheumatic fever or cardiac disease as in a control group of similar size, but that in the operated patients the span of life and period of economic usefulness may be decidedly increased. In other words, the breadth of life may be measurable enlarged by our therapeutic and prophylactic procedures even though the eventual mode of termination may be the same.

To whom, then, must we turn for the eventual solution of many of the problems of cardiac disease? The answer seems obvious. To the physicians and special workers among cardiac patients. The organization of Heart Associations and of special cardiac clinics in various cities of the country is but an expression of the recognition of the necessity for co-operative effort. Eventually society which will furnish the financial support for these organizations will ask whether the expenditure of funds has been justified by results. At present no machinery exists which can give a satisfactory answer to this question. It,

therefore, behooves these Associations to make the obtaining of information in respect to various phases of heart disease a large part of their program.

Let it be immediately acknowledged that the making of accurate observations is a laborious task, and that the recording of these observations is still more laborious. The first work must be done and is being done by physicians and special workers, the second, may be facilitated to a large extent by trained secretarial assistants. At this point Heart Associations with sufficient funds at their disposal might well supply assistance to those institutions which are willing to help by studying their patients in a manner that would lend itself to co-operative documenting. After several years work, charts for such documenting have been elaborated by a special committee of the New York Heart Association.

The objection is often raised that these charts, as they stand today, are too long and too complicated. It was not to be expected that every space would be filled out for every case. Naturally a purely degenerative type of disease requires different treatment in practically all respects than an infectious type. Intelligent discrimination should be applied to history-taking and recording as well as to therapeutics. The blanks had to be so constructed that they lent themselves to the registering of information from all types of cardiac disease, also to the co-relating of this information from many points of view. They were prepared under the advice of statisticians for the statistical treatment of all types of cardiac disease. A little training and experience in their use has convinced more than one objector of their practicability and that time is saved and the records of different cases are more comparable than when each examiner is following his own individual plan. An analysis of 1,000 cases on them is now under way, and the experience gained in this work is immediately available for the extension of their use. In the survey of certain groups of school children and in the follow up of a large number of cardiacs these charts have proven most helpful.

There is today a tendency towards fusion of Heart Associations and Tuberculosis Associations. This has resulted in part from an effort to reduce to a minimum the number of public health organizations, for it seems that in many respects the same machinery and methods may be employed in the treatment of tuberculous and cardiac patients. But it should be kept in mind that the problems in the two conditions diverge at many points. The only positive information in reference to cardiac disease comparable to that concerning tuberculosis is in the diagnosis and treatment of syphilis as it involves the circulatory system. The treatment of rheumatic infections of the heart very probably rests upon the same general therapeutic principles that have

been elaborated for tuberculosis, but the final verdict remains for the future to render. As the Tuberculosis Associations take over the cardiac work, it is well for the directors to keep in mind that new problems are presented to them. In general, unqualifiedly proven methods of prophylaxis and treatment do not exist, nor is there statistical machinery to furnish positive information concerning many of these moot points. There should, therefore, be added to the work of all organizations having to do with the prevention and relief of heart disease a department the special function of which is to coordinate efforts in obtaining useful information in reference to circulatory diseases. The formation of special cardiac clinics and periodic examination of apparently well persons will afford many opportunities for detecting various types of heart disease much earlier than has been possible in the past. These opportunities also carry with them the obligation for giving proper advice concern-

ing specific as well as general prophylactic and curative measures. In diseases of the circulatory system entirely new problems will be presented to the physician, for in the past most of the patients have not applied for medical assistance until their cardiac capacity was diminished enough to prevent them from carrying on their daily tasks.

The urgency of providing means for furnishing answers to these questions is not, therefore, imaginary or over idealistic. It should not in any way interfere with work already in progress or diminish the efforts at present being expended in the treatment of patients with cardiac disease. A constant attempt to gather facts and correlate the results of our work would, on the other hand, place us in a more favorable position to advise our patients properly, to know whether our time and money were being most effectively expended, and finally, to project more intelligently our future plans.

## THE ORGANIZATION OF THE CARDIAC CLINIC\*

By JOHN WYCKOFF, M.D.,

NEW YORK CITY

THE term Clinic in the United States is used to designate two types of organizations. In Europe, and now increasingly here, a clinic is known as a unit, general or specialized, complete for the diagnostic study and treatment of disease, in both the ambulatory and bed phases. In this country, a clinic is more usually considered to be an outpatient dispensary for the diagnosis and treatment of ambulatory patients. The organization of a clinic, in this latter interpretation, is the subject of this paper.

Clinics may be more or less specialized. They may be general or have such a gross subdivision as General Medicine, or General Surgery, such divisions may be subdivided into clinics for the various specialties in medicine or surgery. In these, patients are studied, diagnosed, and treated for a particular disease or group of diseases. The group classifications may be anatomical, as in an eye clinic, etiological, as in a tuberculosis clinic, or by age groups, as in a pediatric clinic. Such classifications are of necessity, arbitrary. For example, the diseases of the eye spring from a variety of causes: trauma, acute infections, chronic infections, diseases of metabolism and others. When the disease of a single organ is due to an underlying cause, such as a chronic infection, other organs may also be affected, for example, a patient with a syphilitic choroiditis may also be suffering from tabes dorsalis, and the question at once

arises whether the patient should be treated in the neurological clinic, the eye clinic, or a syphilitic clinic. Furthermore, when groups are based upon structural classifications, they may call for different forms of treatment. In a neurological clinic, one may meet patients with diabetic neuritis, tic douloureux and muscle atrophies following acute anterior poliomyelitis, all neurological cases, they need for treatment, however, the expert care, one of a specialist in diseases of metabolism, another of a neurological surgeon, and the third of an orthopedist, beside the neurologist.

These well-known difficulties in the arbitrary division into groups of patients for diagnosis and treatment frequently give rise in the minds of thoughtful men and women, as well as those not so thoughtful, to questions as to the advisability of such specializations not only in public but also in private practice. Such criticism is useful. Arbitrary groups based on any form of classification, must not lose touch with other branches of medicine or surgery. There can be no specialty independent of others.

In spite of such criticism, based upon obvious defects of a group system, specialization continues to grow. It may be possible for an occasional superman to know the essentials of progress in all fields, but most of us cannot hope to do so. If patients are to get the benefit of the real advances of medicine, some physicians must work in groups, keeping in touch as much as possible with all fields, but keeping a particu-

\*Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 13 1925

tions and make the best use of them. About seven thousand patients per year are now under the care of various groups of physicians in 48 different cardiac clinics in New York City. There is already a certain degree of co-ordination between many of these groups in that meetings are held and opinions and experiences interchanged, but it may be asked whether, with the present plan of procedure, we shall, at the end of five or ten years, have made much progress in the solution of any phase of the cardiac problem. A regrettable feature of the whole situation is that with the present lack of mutual co-operation, we shall be unable to determine either our rate of progress, or lack of progress, if such exists.

Heart Associations or physicians in other cities of the state might conceivably be able to co-operate more effectively than do those of the metropolis, for the size of the problem among millions of people makes organization complex and cumbersome. To the worker in smaller places we may recall that Trudeau did more than any metropolitan physician to point the way to proper treatment of tuberculosis, and Sir James MacKenzie, after experience both in the country and in London, selected St. Andrews as a more favorable place to study the life history of chronic cardiac disease than he found in a London hospital. The recent work of Kaiser in following a large group of tonsillectomized children and comparing them with a similar group of unoperated ones, shows how a study of clinical material may help us form an opinion of certain prophylactic measures.

At this point we may digress a moment to indicate some benefits to be obtained from the study of the relation of tonsillectomy to rheumatic fever and cardiac disease. It may be that eventually among a group of tonsillectomized individuals there will be as large a proportion having rheumatic fever or cardiac disease as in a control group of similar size, but that in the operated patients the span of life and period of economic usefulness may be decidedly increased. In other words, the breadth of life may be measurable enlarged by our therapeutic and prophylactic procedures even though the eventual mode of termination may be the same.

To whom, then, must we turn for the eventual solution of many of the problems of cardiac disease? The answer seems obvious. To the physicians and special workers among cardiac patients. The organization of Heart Associations and of special cardiac clinics in various cities of the country is but an expression of the recognition of the necessity for co-operative effort. Eventually society which will furnish the financial support for these organizations will ask whether the expenditure of funds has been justified by results. At present no machinery exists which can give a satisfactory answer to this question. It,

therefore, behooves these Associations to make the obtaining of information in respect to various phases of heart disease a large part of their program.

Let it be immediately acknowledged that the making of accurate observations is a laborious task, and that the recording of these observations is still more laborious. The first work must be done and is being done by physicians and special workers, the second, may be facilitated to a large extent by trained secretarial assistants. At this point Heart Associations with sufficient funds at their disposal might well supply assistance to those institutions which are willing to help by studying their patients in a manner that would lend itself to co-operative documenting. After several years work, charts for such documenting have been elaborated by a special committee of the New York Heart Association.

The objection is often raised that these charts, as they stand today, are too long and too complicated. It was not to be expected that every space would be filled out for every case. Naturally a purely degenerative type of disease requires different treatment in practically all respects than an infectious type. Intelligent discrimination should be applied to history-taking and recording as well as to therapeutics. The blanks had to be so constructed that they lent themselves to the registering of information from all types of cardiac disease, also to the co-relating of this information from many points of view. They were prepared under the advice of statisticians for the statistical treatment of all types of cardiac disease. A little training and experience in their use has convinced more than one objector of their practicability and that time is saved and the records of different cases are more comparable than when each examiner is following his own individual plan. An analysis of 1,000 cases on them is now under way, and the experience gained in this work is immediately available for the extension of their use. In the survey of certain groups of school children and in the follow up of a large number of cardiacs these charts have proven most helpful.

There is today a tendency towards fusion of Heart Associations and Tuberculosis Associations. This has resulted in part from an effort to reduce to a minimum the number of public health organizations, for it seems that in many respects the same machinery and methods may be employed in the treatment of tuberculous and cardiac patients. But it should be kept in mind that the problems in the two conditions diverge at many points. The only positive information in reference to cardiac disease comparable to that concerning tuberculosis is in the diagnosis and treatment of syphilis as it involves the circulatory system. The treatment of rheumatic infections of the heart very probably rests upon the same general therapeutic principles that have

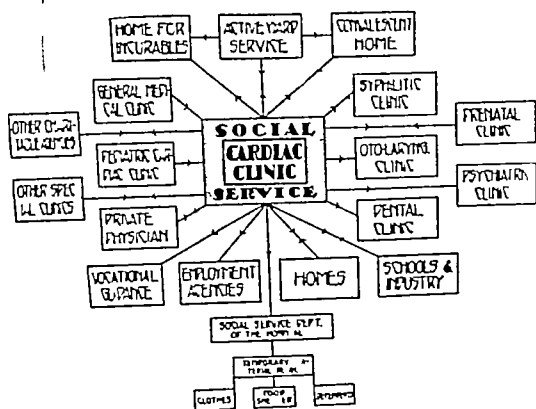

FIG I

Diagram to show the relation of a cardiac clinic to outside agencies, the connecting line of liaison maintained between the social service part of the clinic

**General Medical Clinics**—The relationship to the General Medical Clinic must be particularly close. Heart disease is a part of general medicine, while the reasons for a special clinic are, I think, obvious, the clinic should keep in close contact with the General Medical Clinic, from which it should receive many of its patients.

**Bed Service**—The relationship to the bed service should also be a close one. Under ideal conditions, the physician in charge of the heart cases in the ward should be in charge of the cardiac clinic. In the ward, one sees but a small cross section of the cardiac's life. There one learns the course and treatment of heart failure, and sees the active types of heart disease, but it is in the ambulatory clinic that one learns the course of chronic heart disease, its management and treatment. If there is a ward service connected with the cardiac clinic, members of the resident staff should have duties in the clinic as well as in the ward. Nothing prevents premature discharge of cases of heart failure or of active heart disease from the ward service so well as a staff which serves both in the ward and in the clinic. Patients referred from the ward to the clinic, or from the clinic to the ward, should be accompanied by a transcript of the essentials of their record while under observation, unless there is a unit record system.

**The Pediatric Cardiac Clinic**—In talking with physicians in charge of adult cardiac clinics, one finds agreement that a difficult problem in keeping touch with cardiac patients is at the time when such patients graduate from the pediatric cardiac clinic. There are many reasons for this. Patients who are under the care of one group of physicians and social service workers dislike a change under any circumstances, particularly so when they are suddenly thrown into a group between the ages of fourteen and sixteen, and at this time many of the patients are in Class 1 and free from symptoms. They have had heart

disease for a number of years and have done well, they frequently have little fear of the disease. Among patients of the usual clinic type, they are beginning to break away from parental guidance and have not yet developed a sense of responsibility, and for these reasons the clinic frequently loses track of these young people, a group for whom probably more constructive work can be done, particularly in the field of vocational guidance, than for any other type. At Mt Sinai Hospital in New York, Dr Marcus Rothschild is handling this problem by the formation of an adolescent cardiac clinic. This clinic takes the children at sixteen and keeps them until eighteen. He is also in charge of the adult clinic. The children are graduated from the children's clinic to the adolescent clinic and here, though they come in contact with a new doctor and social service worker, the patients are only a little older and many of them their old friends. In this environment, they are happier, and when, two years later, they graduate into the adult clinic, with the same staff and social service worker, their continued attendance is much more likely.

**Department of Health**—Little is known as to the rôle which scarlet fever, diphtheria and measles play in causing chronic heart disease. It would be well if patients who, while in the communicable disease hospital, develop signs or symptoms of heart disease, should be discharged to a cardiac clinic for further observation and treatment.

**Psychiatric Clinic**—The psychiatric clinic is frequently an aid to the cardiac clinic, not only to find the cause of certain cardiac neuroses and to attempt to lead the patient out of his troubles, but also in cases of organic heart disease, to differentiate clearly between symptoms due to heart disease and those of neurogenic origin.

**The Pre-Natal Clinic and Obstetrical Service**—A cardiac clinic receives many cases from a pre-natal clinic, as heart disease is sometimes first discovered during a pregnancy, and itself must refer many of its younger women to such a clinic when they become pregnant for observation during pregnancy, and for confinement. With close co-operation between these two clinics and the obstetrical service, we believe many lives of mothers and babies are saved.

**Syphilitic Clinic**—In an adult clinic, there are always a number of cases of syphilitic heart disease. It is frequently more convenient to have their anti-luetic treatment given in a syphilitic clinic. However, there should be close co-operation between the two if the patient is to derive the greatest possible benefit. A cardiac clinic should also have referred to it from the syphilitic clinic any cases of syphilis having organic heart disease.

**Otolaryngological Clinic**—If there is no otolaryngological department in the cardiac clinic,

lar eye on newer methods of diagnosis and treatment in some limited field, moreover, in working with large numbers, a distinct economy of time and effort is effected by handling in groups patients with the same or similar disease calling for more or less uniform methods of diagnosis, management and treatment, and I believe this is particularly true of heart patients. In opening, I have tried to point out some of the dangers of specialization, so that we may take heed to avoid them in our consideration of the organization of a cardiac clinic

The first clinic in this country for ambulatory cardiacs was established in 1911, by Dr Hubert V Guile, in Bellevue Hospital. It was begun because the Social Service Department of the hospital felt that the number of returns of cardiac patients to the wards could be diminished if the patients could, upon discharge, be cared for in a clinic less crowded than the General Medical Clinic, and manned by physicians who would have time to become interested in the special problems of the heart patient

#### FUNCTIONS OF CARDIAC CLINIC

The functions of a cardiac clinic, briefly stated, are to keep the ambulatory patient, with organic heart disease, in the best possible health for as long a time as possible. To do this properly, two separate and distinct processes must be carried out

- 1 A diagnosis must be made

- 2 Treatment must be instituted and maintained

Not only should a first, or working, diagnosis be made, but each time that treatment is changed or continued it should be only because the facts upon which the original diagnosis had been made have been reviewed, their correctness considered, and the question as to whether the status of the patient has changed

**Diagnosis**—A complete diagnosis should consist of a cardiac diagnosis and a diagnosis of factors influencing the heart condition, both medical and social. The cardiac diagnosis should be made under the following heads: Etiological, Structural, Pathological-physiological, and the patients should be classified as to amount of cardiac reserve. Under "other medical diagnosis," should be considered any other change of structure or functions, its cause and its bearing on the heart condition. The social diagnosis should include home environment, habits, financial status, responsibilities, and occupation

**Treatment**—The matter of treatment also demands subdivision

- 1 *Medical treatment* of the heart itself is undertaken with the idea of increasing or preventing the loss of cardiac reserve by

- a Treating the cause, or etiologic treatment
- b Treating the changes in structure (a rare possibility)

- c Treating changes in the pathological physiological condition, such as controlling the ventricular rate in auricular fibrillation with digitalis, or by reinstituting regular sinus rhythm in a patient with auricular fibrillation with quinidine

- 2 *Treatment of other purely medical conditions*, other than cardiac, which influence the heart

- 3 *Social treatment* Alleviating or eradicating improper home environment and bad habits, helping to relieve financial handicaps, and removing responsibilities, and aiding in the modification or change of occupation.

**Treatment Plan**—After the diagnosis has been made, the physician and social service worker should, in conference, decide upon a treatment plan in which cognizance is taken of all diagnoses and all forms of treatment indicated

With a very few patients, one individual working alone can accomplish a great deal if he works hard, is resourceful, and uses all the agencies at his command. But, as the number of patients increases, he needs help, and as soon as he has even one person to help, there must be organization or there will be duplication of effort. Such organization must be considered in two ways

- 1 The relation of the clinic to outside agencies

- 2 The internal organization of the clinic itself

Outside agencies related to the cardiac clinic must be classified as

- 1 Those that refer patients to the clinic

- a For diagnosis

- b For diagnosis and treatment of their heart condition

- 1 Referred completely

- 2 Referred for only cardiac treatment, returning to original agency for treatment or care of another sort (e.g. Pre-Natal Clinic)

- 2 Agencies to which the clinic refers patients

- a For diagnostic procedures

- b For medical therapeutic procedures

- c For social care or management

If the cardiac clinic is a part of a general hospital, many of these agencies may be a part of the hospital, but we shall consider them as outside agencies, as we are thinking of the cardiac clinic as a unit by itself

The number of such outside units with which the clinic must co-operate and keep in touch varies. I will discuss briefly the agencies with which one clinic is co-operating, as fairly representative of the connections a cardiac clinic in a city should have. I think it is fair to say as a usual thing, it is best if a cardiac clinic be maintained as a part of an out-patient department in a general hospital, so that all the clinical and laboratory relationships and opportunities for consultations on which efficient cardiac work may depend are represented

the physician and she should take up the case with the physician, making suggestions as to aid. She should not undertake such aid without the direction of the physician, except in emergency. On the other hand, the technique of such work should be left in her hands, she should be trained to do such work efficiently, and should usually not be interfered with in carrying it out. Notes of her observations and her activities should appear on the clinic chart. They should not be kept in a separate file in the social service department of a hospital, but should be entered directly on the patient's chart, as they are a definite part of the history and necessary for complete and correct diagnosis.

In small clinics, she may have to act as file clerk, but in large clinics (although she must have free access to the charts), this should not be part of her duties. She is a specially trained worker who, presumably, is paid in proportion to her training and should not be required to waste hours of time doing work which an unskilled worker may do. Her time during clinic hours should be spent interviewing patients and talking over the problems of the patients with the doctors in charge, and in consultation with the doctors making her plans for work during the following week.

*The Internal Organization of the Clinic*—The primary objects of the organization are

- 1 To make as complete and correct diagnosis as possible
  - a By determining certain facts in the clinic
    - History given by the patient
    - Results of physical examination, including X-ray and electrocardiography, if available
  - b By having available facts learned from without the clinic
  - c The grouping of these facts together in some permanent form and uniform manner so that the physician in a brief time can correlate and interpret the observations
- 2 To assure intelligent treatment in the clinic and prompt reference to proper outside agencies for treatment
- 3 To facilitate the follow-up of these cases both in the clinic and at home so that diagnoses may be checked and the results of treatment noted

That such observations may be made, set down, and treatment instituted, the clinic must have

- 1 A certain minimum of physical equipment
- 2 An organized system of records
- 3 A staff

*Equipment*—A minimum physical equipment as outlined by the Committee on Cardiac Clinic, of the New York Heart Association, should consist of

Proper waiting room and examining room

Files, furniture and stationery

Thermometer, scales, sphygmomanometer

Facilities for routine urine examination, blood counts, and the collection of blood for chemical and serological examinations

While not an absolute necessity, facilities should be available for fluoroscopy by the physician in the clinic, and for teleoroentgenographic and electrocardiographic examinations. In adult clinics, an ophthalmoscope should be available.

*The Record*—Since heart disease is chronic and observations are made frequently over a considerable period of years, and as memory is short, it is essential that all observations should be written down upon a record. They should be noted as briefly as is consistent with accuracy and the system of notation should be as uniform as possible. First, as to the location of information of the chart, so that one knows where to turn to find such information, and second, as to nomenclature, so that as far as possible, similar observations and procedures will always be described in the same way. Furthermore, from the standpoint of the cardiac problem as a whole, all cardiac clinics should use the same record form, the same nomenclature and criteria for diagnosis, otherwise it will be impossible to gather together the data from all clinics for statistical study. The necessity for statistical study cannot be overstressed. Many fundamental questions concerning heart disease can be answered by no other means. Modern medical principles of treating the patient as a whole require that all the records of each out-patient be filed together. A central record system needs good administrative management in order to be effective, but it is far superior to the old plan in which each special clinic had its independent record filed by itself. If such a record system is used, all cardiac diagnoses must be indexed and cross-indexed if they are to be of real use as a source of information.

*Staff*—The clinic staff should consist of the Medical Staff

Social Service Staff

Technical Assistants (if laboratory work is carried on in the clinic)

Clerical Assistants

The duties of the Medical Staff are to take the medical histories, make physical observations, interpret and correlate the facts so obtained with facts brought to them from laboratories, other clinics, the patients' homes and places of work and outside agencies, from these to arrive at a diagnosis, and institute treatment. They should be responsible for the proper entry of all observations on the chart, though the actual making of the entries should be done by clerical assistants. In large clinics, their work may be more specialized, one or more acting in a supervisory capacity, others attending to details. They should

there must be close connection with such a service, both ambulatory and bed, not only for tonsillectomies in patients with diseased tonsils, but to search for diseased accessory sinuses, middle ears and sometimes mastoids, and to undertake the proper means for their cure

*Dental Clinic*—The same relation obtains with a dental clinic. Large cardiac clinics may find it saves much trouble to have a dentist in attendance

*Laboratory*—Besides the routine laboratory examinations done in the clinic, a connection should be made with a laboratory to make special examinations when they are indicated. X-ray and electrocardiographic facilities should be arranged for in this manner if they are not available at the clinic itself

*Convalescent Home*—The convalescent home refers patients to the clinic whom it has received from the ward service. The clinic should be able to send many patients direct to the convalescent home for periods of rest as prophylactic against heart failure. The clinic should keep in mind that a convalescent home is not a refuge for the terminal cases, only patients who may have reasonable hope of having their cardiac reserve increased by convalescent care should be sent to the home. This matter cannot be overstressed. Every worker in a heart clinic is constantly being pressed to do something for the heart patient who is passing into that state of markedly diminished cardiac reserve, where he has symptoms of failure when at rest and where his limitation of effort is so great that he is only able to sit up in a chair or possibly walk to his meals. Such patients are usually discharged from medical service of hospitals. They break down at once in the usual tenement, the clinic worker knows if they are readmitted to the ward they will be discharged again in a short time, and it is a great temptation to send them to a convalescent home. At such a home, they may be able to live within their reserve for several months, but after that time they become bed cases. They should never be sent to a convalescent home. Such homes, as said before, should be rigidly reserved to give the needed rest to the cardiac with some future

*Home for the Permanently Disabled*—A great need, and most difficult to meet, is the disposition of patients who have become permanently disabled. A home for these cases should be available to a clinic. Each year, a number of its patients quietly slip into the class which needs such an institution. Refuges of this sort should be called hospitals, never homes for incurables

*Employment Agencies*—It is frequently necessary to obtain employment for patients or change the employment of those at work. This branch of the work is important and delicate. Patients must be fitted to their occupations with the greatest care. Judgement must be used by all

agencies. The physician must know, as far as possible, the physical potentialities of his patient, the social service worker his past history as to reliability, honesty and willingness to work, the employment agency the character of the work, the effort it entails, and its hygienic aspects. Too hurried and inconsidered placements of heart patients in industry result in failures of the patients to make good, which of course increases the difficulties of the employment agency in placing other patients, it may also result in the physical breakdown of a misplaced cardiac, and entail a long period of convalescence. In large cities, a single agency securing employment for all cardiacs would be more efficient than several bureaus working independently

*Vocational Guidance*—Young cardiacs should, as far as possible, be guided into a life work which will require a minimum of physical effort and little exposure. For such occupations patients need training and the cardiac clinic should have the co-operation of an agency giving vocational guidance and training

*Private Physicians*—Private physicians who refer patients to the clinic, should give information concerning the past history of their patients to the clinic, and the clinic, on its part, should be scrupulously careful to let the physician know of the progress of his case

We have enumerated and briefly described the outside agencies with which a cardiac clinic must co-operate, if this is to be done successfully, a close liaison must be maintained between the patient, those agencies and the clinic. The details of their coordination is the duty of the Social Service Department of the clinic.

*Social Service Department*—What his staff is to the commanding officer in the army, the social service worker should be to the chief of a cardiac clinic: intelligence, liaison, operations and, in smaller clinics, possibly supplies—though this should not be the duty of this department. The social service worker should have available information concerning the physical and mental condition and home environment of the patients; data concerning their education, industrial relationships, finances, and willingness to co-operate. Such a worker should be in touch with all agencies of possible help to the cardiac, and should keep the physician informed as to new developments in such agencies

As directed by the physician, she should carry out relief for the patients. Whether or not a special type of relief is to be instituted is the problem of the physician, the technique of the procedure should be left to the social service worker. There is a tendency in many clinics not to observe these distinctions of function. The social service worker is not trained or expected to know the physical potentialities of any case, but because of her close contact with the patient she should learn of his needs in greater detail than

*Distancing*—Regularity of attendance and a complete follow-up system is essential if the best results are to be obtained. In clinics in large cities, this is impossible to accomplish unless the patients admitted to the clinic are limited to localities accessible to the clinic. Patients living in districts nearer other clinics should not be admitted, but should be referred to the other clinics, and regular patients moving into other districts should promptly be transferred, each of course, with a transcript of his record. It is a great temptation not to do this, particularly as the patients dislike the transfer, but unless it is done, the social service worker's time quickly becomes so taken up in traveling that she is unable to accomplish her work, the patients become irregular in their attendance because of the distance to the clinic and they do badly. One further word about regularity of attendance: Patients who, through lack of interest and carelessness persist in clinic non-attendance, except when they feel ill, and after several warnings, should be dropped from the clinic and only re-

admitted when they give evidence of willingness to co-operate.

The organization which I have discussed has as its chief purpose the relief of the patient. There are two by-products which go with such relief, if it is efficiently done: the first is clinical research, and the second the education of the clinic staff. Dr. Dublin has pointed out this afternoon the paucity of data at hand concerning the fundamental problems of heart disease. For this data to some extent, we must look to the cardiac clinics. New physicians coming into the clinics must be given an opportunity to learn not only physical signs, but the progress of heart disease and the results of treatment instituted. These two by-products of the clinic are accomplished, I believe, in direct proportion to the amount of accurate detail which appears on the record chart and, since that is essential if the patient is to be properly diagnosed and treated, the three desired objects, proper care of the patient, research, and education of the clinic staff, are dependent on each other.

## Deaths

BRASLAW, ABEL, New York City, New York University, 1889; Fellow American Medical Association, Member State Society. Died October 19, 1925.

BROWNELL, WILLIAM HENRY, Utica, New York University, 1882, Fellow American Medical Association, Member State Society, Physician Faxton Hospital. Died August, 1925.

CARR, WILLIAM, New York City, Bellevue Medical College, 1872, Fellow American Medical Association, Member State Society, Consulting Oral Surgeon Bellevue Hospital. Died October 15, 1925.

COX, CHARLES NEWTON, Brooklyn, University of Pennsylvania, 1883, Fellow American Medical Association, Fellow American College of Surgeons, American Laryngological, Rhinological and Otolological Society, American Otolological Society, Member State Society, Brooklyn Pathological Society, Consulting Laryngologist and Otolologist Bushwick Hospital, Consulting Otolologist Long Island College and St. Mary's Hospitals. Died October 8, 1925.

DELPHEY, EDEN VINSON, New York City, College of Physicians and Surgeons of New York, 1889, Fellow American Medical Association, Member State Society, New York Academy of Medicine, American Electrotherapeutic Association. Died October 22, 1925.

GRIBBON, HENRY ALEXANDER, Poughkeepsie, University and Bellevue Medical College, 1899, Fellow American Medical Association, Fellow American College of Surgeons, Member State

Society, Alumni Association Post-Graduate Hospital, Attending Surgeon Vassar Brothers and Samuel Bowne Hospitals. Died October 18, 1925.

HEYMAN, MARCUS BABCOCK, New York City, New York University, 1890, Fellow American Medical Association, American Psychiatric Association, American Public Health Association, New York Society for Clinical Psychiatry, New York Neurological Society, New York Academy of Medicine, Member State Society, Consulting Physician U. S. Veterans' Hospital No. 81 and Broad Street, Superintendent Manhattan State Hospital. Died October 7, 1925.

KUDLICH, HERMANN F., New York City, Vienna, 1869, Member State Society. Died September 26, 1925.

METZGER, JULIUS I., New York City, College of Physicians and Surgeons of New York, 1882, Member State Society. Died September 29, 1925.

MILES, GEORGE WILLIAM, Oneida, Starling, 1879, Fellow American Medical Association, Member State Society. For many years Secretary of the Madison County Medical Society. Died October, 1925.

NEWLAND, FRANK H., Clifton Springs, Cleveland Homeopathic, 1902, Member State Society. Died September 16, 1925.

SEELEY, JENNIE GRAY, Ithaca, Syracuse, 1903, Member State Society. Died September 4, 1925.

be relieved, as far as possible, from work that can be done by lay workers. Another duty of the medical staff, helped by the social service worker, is to enlist the intelligent co-operation of the patient. This can be done best by educating him as to his limitations and explaining to him as far as possible the reason why he is handicapped.

The duties of the Social Service Staff have already been described.

If laboratory work is carried on in the clinic, some of it may be done by the technical assistant, e.g., the electrocardiographic technician, the interpretation of their observations is, of course, the function of the Medical Staff.

Clerical assistants, either paid or volunteer, should be used for filing and indexing histories, filling in such data as name, address, age, sex, etc., and intelligent volunteers can easily be trained to make observations as to temperature, height, weight, certain measurements, vital capacity, etc. They should also enter on the charts, from dictation, the results of physical examinations, in short, do any work that does not require the special training of a physician or social service worker.

While the subdivision of the labor of the clinic should allow the trained experts to conserve their time, it will defeat its purpose unless there is proper coordination. To function properly

- 1 All workers in the clinic must have well defined duties
- 2 These duties should be performed in proper sequence so that
  - a It becomes a clinic routine.
  - b The latest data may be obtained before treatment is instituted. A record should be kept of all their observations and instituted activities

Figure 2 shows the internal organization of one clinic following these general principles.

The subdivision into certain groups for medical observation and treatment, is a detail which would vary in different clinics. On paper, this organization may look complicated. However, after the second or third visit of a patient to the clinic, the patients proceed from station to station without direction, they are handled without hurrying, quickly, and without long waits. Frequently, ninety patients are cared for in two and a half hours. It will be seen that upon the first visit the patient has his history taken, a general physical examination is made, laboratory specimens collected and temporary medical treatment is instituted. During the ensuing week, a home visit is made by the social service department, and social, economic and industrial facts are obtained. On his return visit, the patient is electrocardiographed and fluoroscoped, a tele-roentgenogram is taken, and he has a nose and throat examination. On his third visit, a dental

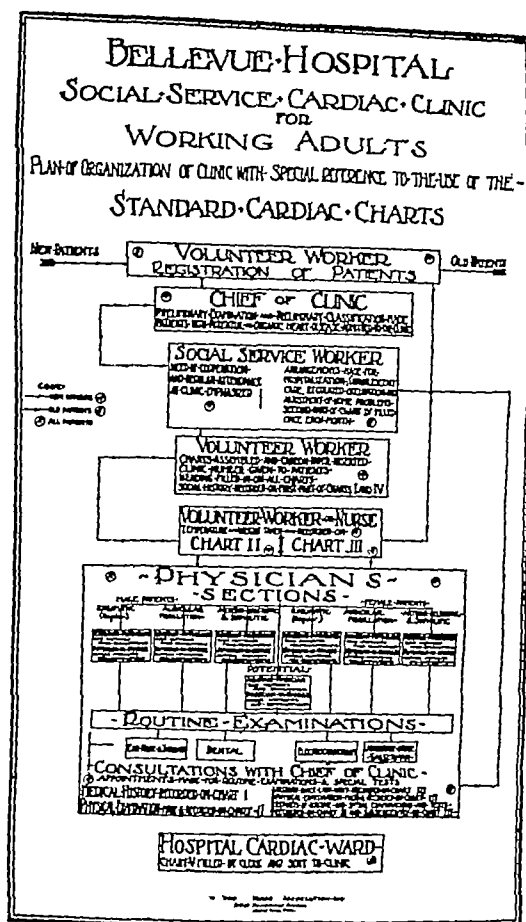

FIG II

Diagram showing the internal organization of one cardiac clinic, illustrating the point that all workers have well-defined duties which are performed in a regular sequence.

examination is made, the data of the previous examination is upon his chart and the physician, with the social service worker, is then able to make a plan based upon careful study of the patient.

It is necessary that patients report regularly. They should be requested to return at definite dates, some weekly, others every two or three weeks, or even less frequently. All active patients should be required to report at least every three months. In our clinic, appointments are made for definite dates, but as yet not for a definite hour. The chief social service worker has a record kept for her by volunteer workers as to the dates of appointments and after each clinic night knows what patients have failed to keep their appointments, these patients are at once written to and asked to come to the clinic the week following. If they do not appear, a home visit is made the next week to determine the cause of non-appearance.

While it is without the province of the Academy to run any sort of a school or post-graduate teaching, its power for good in stabilizing this work and distributing a great fund of information to those contemplating study here, places it in an enviable position

The plans which are proposed for an easier access to the library and an even better co-operation between fellows who wish to secure books and literature from the librarian are most commendable. The last edition of the *Academy Bulletin* suggests this in greater detail

There may still linger in the minds of some a doubt as to whether the most fortunate site for the Academy is its new location? Matrimony offers the same problem and after all maybe it is merely a matter of adjustment

We are reasonably sure that all who have contributed in both time and money to the new Academy will take a civic pride in supporting its upkeep

Any metropolis growing as rapidly as New York cannot make plans anticipating a distant future. We outgrow them almost before they are realized, and the idea of erecting any building in perpetuity must ever be a dream

So the men of the city and state again join in congratulations and thanks to their fellow officers who have been instrumental in establishing the New York Academy of Medicine in new and better quarters, together with the privilege and opportunity for greater good to the whole medical profession

---

## THE DISTRICT BRANCH MEETINGS

We have attended all the District Branch meetings, and have enjoyed every one of them, but we dare not try to judge which one was the best. Each carried out some feature of its program better than the others, and by combining the excellent features of all the programs, we can visualize the ideal meeting

We are aware that any system of forecasting has its limitations. Consider the town in which the meeting shall be held. The Branch meeting whose attendance showed the greatest per cent of increase over that of last year was held in the most inaccessible place, but automobiles triumphed over the limitations of time and space, and physicians evidently thought that the beauty and repose of a mountain hotel are more seductive than the allurements of a great hospital in a large city where the falling off of attendance reached its highest point

The meeting in the mountain hotel was characterized by sociability. The members brought their wives, and there was time for getting acquainted with one another. The whole atmosphere of the place tended toward sociability, and the corridors with their attractive window seats and divans invited acquaintances and friendships—and those, after all, are among the most valuable products of the District Branch meetings

The best assembly room was that which was equipped with a stereopticon, and could be darkened readily. The visual method of imparting information is the most effective, for the eye is more than equal to the ear as an avenue of entrance of ideas to the brain. Speakers like to use lantern slides to illustrate their talks, and great is the satisfaction of both speaker and audience when the pictures are shown clearly

We might make a whole long editorial on

the use of lantern slides in association with a medical lecture, but we will only say that the model set of slides which we saw was made up of diagrams and letters which were so large and plain that they could be easily read from any part of the assembly room

The best program of the Branch Societies gave abundant time for the presentation of the activities of the State Society. One of the essential features of a Branch Society meeting is the presence of the President and other officers of the State Society, and the opportunity to hear and meet the officers is deeply appreciated by the members. The most satisfactory program divided the time about equally between State Society problems and scientific subjects

The ideal District Branch meeting had one of the major activities of the State Society on its program. Graduate education is a subject which is of vital interest to every County Society, and it had been formally recommended to the Branch Societies by vote of the Committee on Public Health and Education. Three District Branches listed the subject on their programs

Another subject which had been recommended by the Committee on Public Health and Education was the movie films on Gastric Ulcer and on Tuberculosis. Four Districts listed the films on their programs

The time available for each meeting was limited. If every ideal feature had been adopted by the committee of arrangements, one day's time would not have been sufficient to carry out the program. Every program gave evidence of careful planning, and the best evidence of the value of the meetings is that those in attendance regretted the shortness of the hours

## LAYING THE CORNER STONE OF THE NEW YORK ACADEMY OF MEDICINE

On October 30th, the New York Academy of Medicine will lay the cornerstone of the new building to be erected at 103rd Street and Fifth Avenue

THE MEDICAL JOURNAL OF THE STATE OF NEW YORK wishes to tender the congratulations of its organized membership

This occasion should be a source of satisfaction to the officers and Fellows of the Academy who have striven so unselfishly these past years to provide a fitting home for the advance of medicine in our great metropolis

The choice of a site, the enlistment of financial assistance from the Carnegie and Rockefeller Foundations and the campaign of raising funds from the membership itself all constituted problems of no mean dimensions

These have been met and successfully solved and now the dream of many years is in the process of being realized

The work of the Academy is primarily one of education. It is fortunately divorced from any political ambition and must necessarily defer matters of this character to the County and State Societies, where they more properly belong

New York has become a great medical center. A clearing bureau is as essential to it as an admission ward to a great hospital. Correlating the medical clinics, providing meetings and sections for every specialty in medicine, and opening its great library to the public and the profession are the outstanding features of its usefulness

# LEGAL

By GEORGE W. WHITESIDE, Esq  
Counsel, Medical Society of the State of New York

## THE GOVERNMENT OF A PROFESSION

To punish the erring members of the legal profession who stray from the paths of rectitude has long been the policy of the Bar Association in New York City. The Committee on Grievances has afforded the aggrieved client a forum wherein he needs no lawyer to plead his cause, and has furnished the lawyer complained against a tribunal composed exclusively of lawyers, who are expert in applying standards of professional honor to the transaction presented for their scrutiny.

This Committee has gained the confidence of the public and of the profession. It is composed of nine unpaid members of the Association, who assume the onerous and unpleasant responsibility of judging their brother lawyers, to the end that public confidence in the profession may not be shaken by failure of retributive justice to the unscrupulous and unworthy member. It is not a mere gesture or an abstract declaration of professional principles that this committee makes. They take specific complaints and dispose of them.

The nine members of this Committee, in the year 1923-24, held forty-nine meetings, which is about an average of a meeting a week. They had brought to their attention in that period, twelve hundred and thirty-four complaints against attorneys. They actually tried fifty-nine cases, and in twenty-nine of these cases requested that disbarment proceedings against the accused attorneys in the Appellate Division be instituted. As a result of their work in the year, the Appellate Division disbarred four lawyers, suspended five for periods ranging from three months to one year, censured one, excused one, and dismissed the proceedings in one case. This large number of complaints so considered covered a broad field. In three hundred and eighty-six cases attorneys were charged with negligence, carelessness, bad advice and collusion against their clients' interests, in two hundred and twenty-six instances they were charged by clients as a result of disputes over fees, one hundred and seventy-three complaints dealt with alleged conversions of money, subornation of

perjury was charged in fifty-nine cases; the use of threats and blackmailing tactics in thirty-nine cases, and improper advertising in thirty-eight cases. These instances cited indicate the type of matters that this Committee considered during that year. This activity was supported, during that time, by three thousand two hundred and twenty-four members, who paid dues of \$182,-655 00, an average slightly under \$60 00 a year per member. The Committee doing this work spent \$19,319 49.

Suppose there had been no such body functioning in the legal profession. Where would all of this professional dirty linen have been washed? How many innocent lawyers accused in twelve hundred and thirty-four complaints would have had their names dragged before the public and their professional reputation besmirched? How many of the guilty would have been punished? Was it worth the money that was spent during that one year and the time of the nine members of that Committee to accomplish the results so essential to the public interests, so important to the profession and so vital to the individual? There are very few cases brought against lawyers in the courts for their alleged shortcomings and there is little publicity that unfavorably affects the profession—suing lawyers does not seem to be a very popular procedure. Has the activity of this Grievance Committee made unnecessary the institution of many such suits against lawyers by aggrieved clients? Has that Committee afforded a fair and inexpensive forum for the aggrieved client to have his grievance justly considered? Has not that Committee done much to elevate the standard of professional honor and save the weak and erring by timely warning from falling from the height of recognized professional responsibility to the depths of professional degradation?

Similar work is done by other bar associations throughout the state.

Is there any food for thought by the medical profession in what the legal profession has thus done and is continuing to do?

## THE PSYCHOLOGY OF MEDICAL INSTRUCTION

The most efficient practical means of imparting instruction to physicians is by means of the programs of medical societies. There are three principal methods of imparting instruction through the programs:

- 1 The spoken lecture
- 2 The visual method in which lantern slides, or diagrams, or other visual helps are used
- 3 The clinical, in which cases are shown, or pathological specimens are exhibited, or vivid case histories are read

The essential features of these three methods are employed in the printed pages of medical periodicals and books.

The spoken lecture reaches the brain through only one avenue—the ear through which words and ideas must go in single file. The visual method adds the broad avenue of the eye, through which ideas may pass in groups, and may pause, or turn back, or resume their entrance at any desired rate. The

use of lantern slides and diagrams not only aids the listener, but they compel the speaker to prepare and arrange his thoughts systematically, and to adapt his words to the concrete images which are seen by the eye.

The spoken and the visual methods are usually impersonal and arouse few or no emotions. In distinction to these two methods the clinical demonstration is personal in a double way. The listeners are always interested in a suffering human being, and if, in addition, they have a similar case in their own practice, the case at once takes on a vital personal meaning to the doctor himself.

A clinical program for a county society is by far the most efficient form of teaching, and the next in value is a talk illustrated with lantern slides and diagrams. A stereopticon is a necessary part of the outfit of a county medical society.

How many county societies own stereopticons?

---

## CASE HISTORIES

The importance of case histories is becoming realized more and more. Histories of cases may have a medico-legal value, and they are necessary for medical progress, and for the good name of both doctors and hospitals.

History writing is one of the most unpopular of all the routine activities of a hospital physician, and our medical surveys have revealed widespread difficulties in getting first-class records made. The leaders in the medical profession insist that histories of their cases shall be written, but the hospital authorities throughout the State would like to see their histories improved.

To most doctors writing medical histories is as irksome as writing articles for the medical journals. We medical editors can appreciate the feelings of the superintendents and managers of hospitals in which histories are not completely written.

There is nothing inherently difficult in writing a good case history. The American College of Surgeons does not require that histories shall be kept to the last detail, as is required in some of the large city hospitals.

Possibly the memory of writing useless details during their interne days is a factor in keeping doctors from writing full histories.

Many are the means adopted by hospitals to secure histories. Some post the names of delinquent doctors, but it often has little effect. One of the most effective means is that of requiring that full histories shall be written before a patient is discharged. The doctor quickly hears from a patient who is told that the reason that she can't get her clothes and go home is that the doctor has not completed his history of her case.

The hospital trustees have a responsibility to provide the means for writing histories. A history clerk is almost indispensable. She will waylay the doctors and get the required facts. She will typewrite the cases so that they can be read, and she will file and index the cases so that they can be utilized in future years.

The American College of Surgeons is doing an excellent piece of public health work in establishing a standard of histories that shall be maintained as a prerequisite to the recognition of the hospitals.

# MEDICAL ECONOMICS

As the members of the Committee on Medical Economics attend medical society meetings and get the opinions and reactions of the members, they are encouraged by the response to the committee's program that was announced on page 942 of the Journal of October first

The subject of periodic examinations of apparently well persons was presented before the Eighth District Branch on October 7th, and aroused enough interest so that several of the county presidents in this district have asked the committee to repeat the discussion before their societies, and help them to arrange for definite programs of action

The medical profession has been so busy with the routine of caring for the sick and disabled that it has given little attention to the well and able-bodied individual. But now so many people are demanding that they have a thorough inventory taken occasionally that the doctors are really taking note of it and are inquiring where they can get a good blank for this purpose. The American Medical Association published a blank and many physicians have been using it. Several states have adopted their own blanks, while many of the counties in this state have endorsed the movement and adopted blanks of their own. The particular form of blank used is of minor importance so long as it contains all the headings and sub-divisions, and will lead the doctor to make a thorough examination. The value of having a good blank and being familiar with it is that one may proceed with a complete examination much more quickly by having a definite routine and always following it. The use of a standard form is desirable because by recording methodically observations as to physical and functional conditions of persons passing through their hands, physicians will acquire increasing skill and keenness in detecting early evidence of preventable and curable conditions, and also because by the general employment of a thorough and complete method of inquiry by physicians the laity will learn to appreciate the importance to their own health of good medical examinations and to expect attention to details of personal hygiene on which continued health so often depends.

There are two points to be emphasized. The first is that we want to get the idea across to the laity, "*Go to Your Family Physician First*." This has been done in many cities and counties by putting on a Health Week Campaign.

The Medical Societies of Onondaga, Albany, and Monroe Counties, and in Yonkers, have recently made the Health Examination campaign

a part of their regular program of public health education, and in each case have taken further steps to work out the details of the campaign with the co-operation of other agencies, particularly local committees on tuberculosis and public health.

The members of the Onondaga County Medical Society voted not only to promote health examinations, but to initiate the campaign by a health examination clinic with its own members to be examined, as was done in Brooklyn, thus setting a good example for the rest of the Community. The Onondaga Health Association is co-operating in this enterprise.

The Albany County Medical Society unanimously adopted resolutions, urging periodic examinations, and appointed a Committee to develop plans in co-operation with other agencies.

The Yonkers Academy of Medicine recently endorsed the health examination campaign and appointed a Committee which will act jointly with a Health Examination Committee of the Yonkers Tuberculosis and Health Association, and a campaign program has been adopted for operation the first of the year, including moving picture publicity, lantern slides, pamphlets, poster exhibits, and newspaper publicity.

At a meeting of the Monroe County Medical Society, a resolution was unanimously passed making the Health Examination movement a part of its program and authorizing the appointment of a special Committee.

The following statistics are of interest in connection with the Health Examination Campaign as carried on during the past 18 months by the Rochester Tuberculosis Association.

Twenty thousand health examination leaflets and 18,000 folders were distributed to industrial plants, including the Eastman Kodak Company, and at the Rochester Industrial Exposition, 1,500 were distributed in the towns and villages, 15,000 pay envelope cards were distributed to employees in smaller plants, and to hotels and lunch rooms, 2,000 posters were distributed to 297 factories, 375 special letters were sent to food handlers, 450 letters to managers of factories, and 316 form letters to physicians in the city. The film, "*Working for Dear Life*" appeared in 17 moving picture houses 140 times, before 35,000 people, 25 employment managers were interviewed, 37 health talks were given and 2 talks by radio by the Chairman of the Health Examination Committee. Two sets of 150 street car cards advertising health examinations were used one month each in the street cars. As a

## BREAKING OF X-RAY APPARATUS

The plaintiff, a woman about 55 years of age, had suffered a right Colle's fracture and had come to the defendant physician for treatment. To aid him in his examination and diagnosis he ordered an X-ray to be made and arrangements were made to meet the patient in the X-ray department of a hospital with which the physician was connected and had the right to use their X-ray apparatus.

At the appointed time the physician met the patient at the hospital and took one X-ray picture of the wrist. He then proceeded to prepare the apparatus for the taking of a second picture, the patient's arm in the meantime lying upon the X-ray table. While adjusting the apparatus one of the control cables broke causing the X-ray tube to fall upon the patient's injured wrist. The fracture was treated by the physician with a subsequent good result, the patient procuring a functioning wrist with some slight impairment in

flexion. Thereafter the patient instituted an action against both the physician and the hospital, charging them with negligence in the taking of the X-ray and claiming that by reason of the breaking of the X-ray apparatus and part falling upon her injured wrist the condition at the site of injury was aggravated, causing her great pain and suffering and permanent disability.

The action came on for trial and at the close of the plaintiff's case was dismissed as against the defendant physician. The trial was continued as against the hospital and submitted to the jury which found in favor of the hospital. The plaintiff thereupon appealed to the Appellate Division which affirmed the judgment in favor of the physician, but reversed the judgment as to the hospital ordering a new trial. The matter was thus favorably terminated in favor of the defendant physician.

## CLAIMED NEGLIGENT OPERATION RESULTING IN LOSS OF KIDNEY

A physician being unable to collect his bill for services rendered in the performance of an operation for the removal of a stone from the kidney, instituted an action against the patient, in which action, as a means to avoid the payment of the bill, the patient interposed a counterclaim of alleged malpractice charging that the physician negligently performed the operation, as for many days after the operation there was a continued bloody discharge resulting in pyelitis and subsequent bilateral pyelitis. The patient further claimed that by reason of the surgeon's negligence it was necessary for him to submit to three additional operations causing the loss of the patient's left kidney.

When the patient sought advice and care from

the physician he was suffering from stones in both kidneys and disease of both kidneys. An operation was performed upon the right kidney and a stone removed therefrom. As in almost all cases where an operation of this nature is performed, there was some bleeding. The operation upon the right kidney was successful and relieved the condition as, at the time of the institution of this action the right kidney was converted into a healthy and good functioning organ.

When the case was about to be reached for trial and the physician pressed his action to recover for the services rendered, the defendant withdrew his counterclaim of alleged malpractice and paid the physician for the services which had been previously rendered.

## UTERINE TUMOR—X-RAY BURN

The plaintiff in this action had been examined by a gynecologist and referred to an X-ray therapist for treatment for a uterine tumor. It was charged that he failed to use due and proper care in his endeavor to cure the plaintiff, in that on the day specified he negligently administered the X-ray, causing her to be burned, which condition would not have resulted had care and skill been used in the administration of the X-ray. The husband also joined in the wife's action, seeking to recover damages for the loss of his wife's services.

The dates of treatment and the dosage administered to the plaintiff were as follows:

Date	Spark Gap	Distance	Filter	Time	Place
May 25	9"	10"	3 mm.	6 min	Over lower abdomen
June 3	9"	10"	3 mm.	6 min	Buttock and sacrum
June 12	9"	10"	3 mm.	6 min	Abdomen anterior

No further X-ray therapy was administered. When the patient returned to defendant on July

10th there was a small area of redness on the abdomen, and on July 10th, 20th and 22nd he administered light treatment by holding over the reddened area a 100 Watt tungsten lamp for a few minutes at a time. There was no break or peeling of the skin and no ulceration. The defendant had advised the patient to return and to continue the light treatment, but the plaintiff did not return after July 22nd.

It was claimed by the patient that a portion of her abdomen was severely burned. However, about the time of trial a physical examination disclosed that there was a slight area about the size of a quarter on the abdomen which showed a slight discoloration, but no other injury.

The action finally came on for trial which lasted three days, and after the introduction of testimony by both sides the case was submitted to the jury, which rendered a verdict in favor of the defendant.

# MEDICAL SURVEY

## NUMBER 17—MONTGOMERY, FULTON AND HAMILTON COUNTIES

**EDITOR'S NOTE**—The information on which this Survey is founded was obtained principally from Dr J S Walton, District State Health Officer and President of the Montgomery County Medical Society, Dr H B Riggs, President of the Fulton County Medical Society, Dr H M Hicks, President of the Fourth District Branch, and Dr Charles Stover of Amsterdam

Montgomery County extends for 30 miles on both sides of the Mohawk River, beginning on the west side of Schenectady County. It has an area of 398 square miles, and a population of 57,928. It has one city—Amsterdam—with a population of 33,524, and nine villages with a total population of 12,350. The largest village—Fort Plain—contains 2,747 people. The county has 12,054 people living outside the cities and villages.

**Physicians**—There are 56 physicians listed in Montgomery County, according to the Directory of the Medical Society of the State of New York, of whom 34 live in Amsterdam, and 24 in ten centers in the rest of the county. The proportion of doctors in the city is 1 to 1,000 of population, and outside the city it is 1 to 1100.

**County Medical Society**—The Montgomery County Medical Society has 51 members, or 91 per cent of all the doctors listed in the county. This is an exceedingly high percentage, and shows a deep interest in medical matters on the part of the physicians of the county. The Society holds monthly meetings which are well attended.

The city of Amsterdam is the center of Montgomery County, medically and geographically. Its doctors are active in medical affairs, and are qualified and equipped to take good care of practically every medical condition that arises, without calling for outside help. The doctors are within easy reach of medical centers in Schenectady and Albany, and they take pride in conforming to the standards of the doctors in the larger cities.

The high standards of medical practice are reflected in the activities of the County Society. Monthly meetings are held, and also the monthly staff meetings of the two hospitals in Amsterdam are in fact clinical meetings of the doctors. The Montgomery County Medical Society has been active in post-graduate medical work since the year 1919, when the Board of Supervisors established a county laboratory with a full-time director and pathologist. This step aroused the

interest of the doctors, and they put on a series of lectures on pathology for which a fee was charged. This course was so well attended and received that the physicians have planned other courses for which fees will be charged. The County Society is thus one of the pioneers in graduate education work.

**Hospitals**—Montgomery County has three hospitals.

1 St. Mary's, Amsterdam	50 beds
2 Amsterdam City, Amsterdam	75 beds
3 Tuberculosis Sanatorium	50 beds

The county has three beds for each 1,000 of population, but provision is being made to double the capacity of St. Mary's.

The two hospitals in Amsterdam are well organized with open staffs. Over two-thirds of the physicians of Amsterdam are listed on the staffs of both hospitals. Each holds monthly staff meetings which are practically meetings of the County Medical Society. The hospitals have adopted a system by which the nurse in charge of each case is authorized to look after its history, and to be persistent in asking the doctor for the necessary items of information. The names of the doctors who do not comply with the requests of the nurses are posted, and as a final resort no patient is discharged until the doctor has completed the history. The result is that the doctors have acquired the habit of writing histories. Each hospital has a training school for nurses.

**Public Health Work**—The official public health work of Montgomery County is done by 10 health officers, of whom 9 are members of the County Society, and 8 have had special courses of instruction. Each health officer outside of the city of Amsterdam serves an average of 2,700 people.

The county maintains a tuberculosis sanatorium with 50 beds, in charge of a full-time superintendent, Dr W A Bing. Clinics are held at regular intervals, and the work is well organized.

A lay county tuberculosis committee is active. It supports an executive secretary and uses most of the Christmas seal money in the support of a summer camp for undernourished children.

The county maintains a public health laboratory in the Amsterdam City Hospital, with a branch in St. Mary's Hospital, and another in the County Sanatorium. The director, Dr J A Dickson, has brought the work up to a high stage of efficiency. He and his staff are at the service of physicians at all hours to give intra-

special feature, a Balopticon was installed in several store windows showing 24 health slides. Articles urging health examinations have appeared periodically in the press.

The second point to be emphasized is that general practitioners should be prepared to take care of their patients when they come.

The public is becoming educated today to demand a scientific and up-to-date attitude on the part of the physician. The present transportation facilities do not require people to employ the doctor around the corner. If they don't get service at home, they go elsewhere. After all, service is what we have to sell, but it must be scientific. The public is willing to pay for the kind of service it demands. It is up to us to render that service and charge for it.

We hear much about the passing of the family doctor. Don't be alarmed. The passing of the slipshod, unscientific bunk dealer is a reality. But the well trained, properly equipped, experienced general practitioner has a field today greater than ever before. He is a good diagnostician. He sees his patient as a whole. He knows his peculiarities and circumstances. He can decide when to refer him to a specialist and when to protect him from the danger which is threatened by a narrowly specialist point of view.

He is not only a physician, but a friend and counselor. He not only knows the normal but he knows the effect upon health of diet, exercise, mental attitude, recreation, family and social life.

His care of cases of typhoid fever, diphtheria, scarlet fever, tuberculosis and malaria has been materially reduced by sanitation and preventive medicine. Social medicine, free clinic, school and industrial medical service tend to encroach upon the field of the general practitioner. But what of such diseases as cancer, diabetes, diseases of the kidney, heart and blood vessels and other organic diseases? They seem to be increasing, or at least not decreasing. Early diagnosis seems to be the step in combating these maladies and early diagnosis cannot be made without examining apparently well individuals. What better plan can one suggest than to advise every individual to go on his birthday and have a competent physician make a thorough physical examination, and have an inventory of his physical assets and liabilities? In this way the early de-

tection of some organic disease or some definite physical impairment of which the person is unaware is brought about. Errors in environment, hygiene and personal habits may be corrected and through this the span of life, which is now about fifty-eight years, will be materially increased.

During the last decade, many agencies, such as health departments, voluntary health organizations, life insurance companies, hospitals, clinics, industrial concerns and individual physicians have been taking more and more interest in the proposition of Periodic Health Examinations of apparently well people.

With the slogan, "Have a Health Examination on Your Birthday," the campaign of the National Health Council started July 4, 1923, and has gained such momentum that its effect is felt by every ethical physician doing general practice in this state and in many other states in the Union.

It is quite natural that insurance companies should be the first to put the idea to practical test because it offers a definite plan for the preservation of human life.

Taking advantage of the publicity given by the National Health Council and the natural attitude of the lay mind which is always looking for some way to avoid employing a physician, numerous health laboratories have commercialized the idea and are flooding the mails with their circulars advertising that for fifteen dollars per year they will make four urinalysis and tell each person just what to eat and how to live indefinitely.

It is high time that organized medicine in all of its branches took definite steps to meet the demands created by this nation-wide campaign.

How can the medical profession be prepared to meet this great change that is coming?

1 The members of the medical profession should each one have a health examination. In what better way can we visualize this important step and show our patients that we practice what we preach?

2 Every County Society should endorse the movement and put on a regular periodic health examination campaign in which the idea is carried to the laity by a proper publicity program. This should be under the direction of the Public Health Committee.

W. WARREN BRITT, *Chairman,*  
Committee on Medical Economics

# DISTRICT BRANCHES

## THE FIRST DISTRICT BRANCH

The First District Branch of the Medical Society of the State of New York is composed of three metropolitan counties—New York, Richmond and Bronx—and five other counties—Rockland, Orange, Westchester, Putnam, and Dutchess. This Branch held its annual meeting on the afternoon of Wednesday, October 14th, in the Vassar Brothers Institute, Poughkeepsie. The President, Dr. John A. Card, presided, and 50 members were present.

Dr. N. B. Van Etten, President of the Medical Society of the State of New York, described the activities of the State Society, and emphasized the civic duties of the physicians. He gave statistics showing the evolution of the civic duties of physicians, especially in regard to the problems of insanity and nursing. Anyone hearing his address would get a new insight into the broad field of influence which doctors should have in community affairs.

Dr. Daniel S. Dougherty, Secretary of the State Society, gave an inspirational address, combining apropos stories and good advice in a most happy way. He urged the leaders of the county societies to report the activities of the societies in the State Journal in such a way that the local newspapers would abstract the news from the Journal.

Dr. Orrin S. Wightman, Editor-in-Chief of the NEW YORK STATE JOURNAL OF MEDICINE, described the plans for making the Journal so interesting and useful that doctors outside the State would want to subscribe to it.

Dr. Wightman also described the Periodic Health Examination campaign which is being conducted by the New York County Medical Society, and announced the forthcoming publica-

tion of the series of lectures on what to look for in making an examination. Abstracts of several of the lectures were published in the Journal early last Spring.

Dr. Joseph S. Lawrence, Executive Officer of the State Society, described the opportunities of the District Branch leaders in promoting indemnity insurance, increased membership, and sociability and friendships among the members of the county societies.

The scientific address of the day was given by Dr. William Francis Campbell, of Brooklyn, Past President of the State Society, on the subject, "The Hernia Problem and Workmen's Compensation," and illustrated his lecture with lantern slides. Dr. Campbell spoke especially on traumatic hernia, and said that it was an extremely rare condition. Nearly all hernias are of slow onset and are the result of a failure of the congenital peritoneal sac to close firmly. A particular strain or an injury was usually given as a cause for a hernia when a patient first notices it, but Dr. Campbell said a hernia was to be considered traumatic and compensable only when six conditions were present:

- 1 The force is adequate to produce the hernia
- 2 The descent of the hernia follows immediately after the injury
- 3 Severe pain comes on at once
- 4 Prostration is at once marked
- 5 A physician is called within twenty-four hours
- 6 The employer is notified within twenty-four hours

The movie film on Gastric Ulcer was then shown, and was followed by the film on Tuberculosis. See page 1012.

## THE SECOND DISTRICT BRANCH

The Second District Branch of the Medical Society of the State of New York comprises the four counties on Long Island. The physicians of the Island are closely united and cooperative. They meet one another frequently in the medical center, Brooklyn, and they have published their own medical journal, the Long Island Medical Journal, for nineteen years. They have had their common organization, the Associated Physicians of Long Island, for over twenty-six years, or longer than the re-organized Medical Society of the State of New York has existed. The same

men who are deeply interested in the Second District Branch are also leaders in the Associated Physicians. The two organizations, therefore, held a joint meeting on Tuesday, October 13th, in the Hempstead Country Club, Hempstead, Nassau County.

The meeting began at 4:30 with a brief business meeting of the Associated Physicians at which the president, Dr. A. D. Jaques, of Lynbrook, Nassau County, presided. This was followed immediately by a meeting of the Second District Branch at which the president of the Branch, Dr. Joseph S. Thomas, of

venous injections and perform other expert services. He also secures numerous autopsies, and preserves the diseased organs. The collection of pathological specimens is rapidly growing, and is at the service of the County Medical Society for Graduate Education teaching.

Clinics are held in Amsterdam in Tuberculosis, child welfare, and venereal diseases. A dental clinic is held in the schools.

The schools of Amsterdam employ a full-time medical inspector, a dental hygienist, and five health teachers who are registered nurses. Public health nurses are employed in the county as follows:

Amsterdam schools	5
Amsterdam public health	4
Amsterdam Metropolitan Life Insurance Co	1
County Tuberculosis	1
Village schools	4
Total	15

## FULTON COUNTY

Medical conditions in Fulton County are similar to those in Montgomery County.

Fulton County adjoins Montgomery on the north. The two counties form a square with an artificial boundary line running east and west. Communication between the two counties is easy and extensive, and the physicians have cordial relations.

Fulton County has an area of 516 square miles, and a population of 44,927. It contains two cities, Gloversville, population 22,075, and Johnstown, with 10,908 population. There are only two villages, and their combined population is 1,782. The population of the county outside the cities and villages is 9,264.

**Physicians**—There are 46 physicians listed in Fulton County,—30 in Gloversville, 11 in Johnstown, and 5 in the rest of the county. There is one physician to every 975 inhabitants of the county.

The civic and medical center of Fulton County is Gloversville, which is about 12 miles from Amsterdam. While the physicians of the two cities are on friendly terms, yet those of Gloversville are independent medically, and have sufficient local talent to take care of their own cases, as do the physicians of Amsterdam.

**Hospitals**—Fulton County has two hospitals:

1 The Nathan Littauer Hospital, Gloversville	55 beds
2 The County Tuberculosis Hospital	35 beds
Total	90 beds

Fulton County has 2 beds for each one thousand of population.

The Nathan Littauer Hospital employs a history clerk, and its staff holds monthly meetings. It has a laboratory with a pathologist in charge, and plans are under way to make the facilities and standards conform to those of the State

Department of Health. This hospital conducts a training school for nurses.

**County Medical Society**—The Fulton County Medical Society has 37 members, which is 80 per cent of the physicians listed in the county. It holds monthly meetings, at which nearly all the papers were given by local men.

The County Society has voted to assume the direction of the Child Welfare clinics throughout the county. Plans are nearly perfected by which the County Society will assign physicians to the several towns, and it is expected that the Town Boards of Health and the State Department of Health will provide the funds to pay the doctors honorariums for examining the children.

**Public Health Work**—The official public health work of Fulton County is done by 9 health officers, of whom 7 are members of the County Society, and 7 have had special courses of instruction. Each health officer outside of the cities serves an average of 2,200 people.

The county has a tuberculosis sanatorium with a superintendent on part time. A County Tuberculosis Committee supports a summer camp for undernourished children.

Gloversville maintains regular clinics in tuberculosis, child welfare and venereal diseases.

**Public Health Nurses**—The following public health nurses are employed in Fulton County:

Johnstown school	2
Johnstown Red Cross	2
Gloversville Public Health	2
Gloversville school	2
Gloversville Metropolitan Life Insurance Co	1
Gloversville Red Cross	1
County Tuberculosis	1
Total	11

## HAMILTON COUNTY

Hamilton County has an area of 1,700 square miles, and extends from Fulton County northward 60 miles into the heart of the Adirondack Mountains. It has a permanent population of 3,970, which is increased many fold during the summer. There is one incorporated village in the county, Speculator, pop 600, and the only place reached by a railroad is Raquette Lake in the extreme northwest corner.

Eight doctors live and practice in the county. The towns of Indian Lake, Long Lake, and Speculator each has given its local doctor a salary of from \$1,200 to \$3,000 for acting as health officer and as physician to the poor.

While there are few doctors in the county during nine months of the year, many doctors go there in the summer and practice among the summer residents.

Hamilton County has no County Medical Society, but some of the doctors have joined the societies of the neighboring counties.

slup in health matters that are now being done by lay organizations

Dr Charles Stover, of Amsterdam, told of the post-graduate plans of the Montgomery County Medical Society. He said that interest in post-graduate medical work began in 1919 with the establishment of a laboratory in the City Hospital, which was soon taken over by the Board of Supervisors. A competent pathologist was employed and a course of lectures was given by Dr Kellar of the Bender Laboratory, Albany. The doctors of Montgomery County are now forming a class of thirty, each of whom will pay \$25 toward honorariums for doctors who will give a series of lectures and clinics. Dr Stover spoke highly of the graduate education plans of the State Medical Society, but said that Montgomery County would continue the plans which had been formed before the State Committee was functioning.

A luncheon was served to the physicians and their wives at noon in the basement of the church, and the afternoon was devoted to the following scientific program.

"A New Type of Obstetrical Forceps," Dr Lyman G. Barton, Plattsburg

"A Lantern Slide and Moving Picture of the Use of the Forceps," Dr W. S. Caldwell, New York City

"The Theory of Circus Movement and Its Application to Auricular Flutter and Fibrillation," Dr Carl R. Comstock, Saratoga Springs

"Fractures—Principles and Treatment, With Lantern Slide Demonstration," Dr David Wilson, Amsterdam

Exhibition of a movie film on Tuberculosis, prepared by Dr Gregory Cole, New York City

The physicians were shown pathological specimens from the County Laboratory, prepared by the pathologist, Dr James A. Dickson.

In the evening a popular meeting was held at which the tuberculosis movie film, prepared by Dr Gregory Cole, was shown. The reel on "Working for Dear Life," prepared by the Metropolitan Life Insurance Company, was also shown. Dr H. J. Hawk, Superintendent of the Mount McGregor Sanatorium, Saratoga County, addressed the meeting on the value of health examinations. About 400 persons were in attendance.

## THE FIFTH DISTRICT BRANCH

The Fifth District Branch of the Medical Society of the State of New York is noted for its excellent meetings. This year's annual meeting was held on Friday, October 9th, in the Marcy Division of the Utica State Hospital. The President, Dr Nelson O. Brooks, of Oneida, and the Secretary, Dr William J. McNeerney, of Syracuse, recorded. Over 100 members were present, although the day was rainy and the roads were slippery.

Morning and afternoon sessions were held with an hour's intermission for luncheon, which was given through the courtesy of Dr Richard H. Hutchins, Superintendent of the Utica State Hospital. The meetings were held in the Assembly Room of the Hospital, which was equipped with a stereopticon containing a reflecting attachment for projecting writings and pages of books.

The members were welcomed by the superintendent, Dr Richard H. Hutchins, who described the development of the Marcy Division of the Utica State Hospital since ground was broken for it six years ago. He spoke of the efforts of the State authorities to provide hospital room for the ever-increasing number of the insane, and said that a more promising method of meeting the situation was to detect the earliest signs of insanity while the disease was in an incipient stage and curable. The staffs of the hospitals were holding clinics for incipient cases with great success, but it was necessary to take a

further step and instruct family physicians in the recognition and treatment of conduct disorders and "nervous" conditions for which the patients nearly always consult their family doctors when the symptoms become annoying. Dr Hutchins offered the facilities of the Hospital to those doctors or groups who would like to study the fundamentals of psychiatry.

Dr Clarence O. Cheney, Assistant Superintendent of the Utica State Hospital, described the good results of treating cases of general paresis with malarial germs inoculated into the blood, and the production of a transient fever. He also mentioned the good results from the use of trypanemine in three-grain doses once a week intravenously. Dr Cheney said that the malarial germs produced a shock which arouses the defensive mechanism of the body to clear up the cortex of the brain from the intercellular inflammation which is the pathologic condition in the early stage of general paresis. The doctor showed several cases of general paresis which had been treated with malarial organisms with very great improvement.

Considerable time was devoted to a description of the various activities of the State Medical Society. Dr N. B. Van Etten, President, described the fundamental conditions which confront the State Medical Society, and showed how the Society was broadening its activities in order to take its proper place among the great civic forces of the State.

Flushing, presided. One hundred members were present.

Dr Daniel S Dougherty, Secretary of the Medical Society of the State of New York, spoke on the business methods of the State Society, and urged the District Branch to support the proposed amendment to the by-laws of the State Society establishing a board of trustees to control the expenditure of the one hundred thousand dollar income of the Society. On motion the meeting voted unanimously in favor of the proposed amendment.

Dr Joseph S Lawrence, Executive Officer of the State Society, spoke on the opportunities of the President of the District Branch to bring the local problems of the county societies to the attention of the Council of the State Society.

Dr Orrin S Wightman, Editor-in-Chief of the New York State Journal of Medicine, spoke of the plans for increasing the field of usefulness of the Journal.

At six o'clock, the members sat down to a social supper, after which Dr N B Van Etten, President of the Medical Society of the State of New York, read a carefully prepared paper on the opportunities for service which are before the State Society.

The scientific program was then carried out, and consisted of an exhibition of the two movie films on Gastric Peristalsis and Gastric Ulcer, which had been prepared by Dr Gregory Cole. These remarkable films showed the X-ray appearance of the stomach in motion in both normal and pathological conditions. Physicians are familiar with X-ray photographs of the stomach, but Dr Cole has "animated" the pictures so that they show the peristaltic waves in a remarkably clear manner. Physicians generally are surprised at the depth of the peristaltic constrictions and the rapidity of their travel down the whole length of the stomach. The two films require nearly an hour to show, and they convey information far more vividly and truthfully than hours of description and still pictures could show.

The films end with an outline of what constitutes a surgical condition and what is medical, and the finale is an animated cartoon of a fist encounter between a surgeon and an internist over the treatment of a case.

The meeting was highly interesting, and the response of the members to the speakers was remarkably enthusiastic.

#### THE FOURTH DISTRICT BRANCH

The annual meeting of the Fourth District Branch of the Medical Society of the State of New York was held on Thursday, October 8th, in the Emanuel Presbyterian Church, Amsterdam. The President, Dr Horace M Hicks, presided, and 75 members were present. The meeting was opened with a brief prayer by the pastor, Rev Lewis A Galbraith.

Dr Hicks in his president's address, spoke of the social and civic duties of a doctor who is well educated in science and well read in literature. The doctor could encourage the rural farmer to improve himself mentally, and also could help him in his problems with soils, fertilizers, insects, and other problems of the farm.

Dr N B Van Etten, President of the State Medical Society, gave an address on the activities of the State Medical Society, and its component district and county societies. He showed the great progress that has been made in the societies during the last five years, and said that he considered himself fortunate to be president at this time when the society was being carried on by five doctors for every one who was at work five years ago.

Dr Daniel S Dougherty, Secretary of the State Society, took "Service" as the subject of an inspiring address. He spoke of the necessity of trying to please the patients, and urged the

doctors to cultivate a manner which inspired confidence and yet is scientific. He said that a patient whom he sent to an eminent specialist was dissatisfied because the doctor had only a chair, a table, and a book case in his office, and the patient was delighted with another doctor who examined her for half an hour with electric lights and mirrors, for he "did a lot for her." Another patient felt that Dr Dougherty was neglecting her because he looked into her ear with only a speculum and head mirror, while another doctor had looked into it with fourteen different instruments. The doctor spoke of the value of an up-to-date equipment, and of the need for a thorough physical examination of every new case.

Dr Dougherty emphasized the need of supplying every county secretary with clerical assistance, for he has to write letters, address envelopes, and do other clerical work which a stenographer could readily do. He had found that county societies always provided the money, even by raising dues, whenever the secretaries had asked for the means to increase the field of usefulness of the secretary.

Dr J S Lawrence, executive officer, spoke on means for increasing the interest in county societies, and suggested four meetings a year as the minimum, and the assumption of the leader-

Superintendent of the City Hospital, said the specimens would be available for use by the Committee on Public Health and Education in the Graduate Courses

The half day scientific program was as follows

"The Differential Diagnosis of Pain in the Right Lower Quadrant of the Abdomen," Dr Harold Blaisdell, Jamestown

"The Surgery of the Handicapped Patient" Dr William D Johnson, Batavia

"Some Solved and Unsolved Problems in Gall-Bladder Surgery," Dr E R McGuire, Buffalo

"The Acute Leukemias," Dr Nelson G Russell, Buffalo

"A Resume of Recent Researches in Cancers," Dr Burton T Simpson, Buffalo

A buffet luncheon was served at noon by the courtesy of the Erie County Medical Society

About fifty members sat down to a subscription dinner which was held in the early evening in the lobby of the City Hospital

The evening program consisted of the moving picture, "Working for Dear Life," and the lantern slides and lectures on "Have a Health Examination on Your Birthday" Dr Britt explained that these were shown for the information of the doctors of the Eighth District Branch, and to show them what could be done in each community to promote Periodic Health Examinations by the doctors themselves

The following officers were elected to serve for two years President, Dr George F Cottis, Jamestown, First Vice President, Dr Thomas J Walsh, Buffalo, Second Vice President, Dr Francis E Fronczak, Buffalo, Secretary, Dr William Warren Britt, Tonawanda, Assistant Secretary, Dr Russell H Wilcox, Tonawanda, Treasurer, Dr Fitch H VanOrsdale, Belmont

## COLUMBIA COUNTY MEDICAL SOCIETY

The annual meeting of the Columbia County Medical Society was held at The Worth House, Hudson, on Tuesday, October 6, 1925 President Charles L Nichols presiding

Members present Drs Collins, Diefendorf, Edwards, Galster, Harris, King, McCormick, Mambert, Maxon, Nichols, Noerling, G W Rossman, C G Rossman, Skinner, Taylor, Van Hoesen, Wheeler, Whitbeck

Dr McCabe, president of the District Branch, and Dr MacFarlane, of Albany, were guests of the Society

The minutes of the semi-annual and special meetings were read and approved as read

The following officers for the ensuing year were elected

President, Henry J Noerling, vice-president, John P Ruppe, secretary and treasurer, Charles R. Skinner, Censors, Louis Van Hoesen, Clark G Rossman, William D Collins, Nathan D Garnsey, Frank C Maxon, delegate to State Society, John L Edwards, alternate, Charles L Nichols

Treasurer's report showing a membership of 35 and a balance in the treasury of \$160.93 was read and accepted

Application for membership of Dr John P Ruppe was reported favorably by the Board of Censors and was unanimously accepted

The secretary was instructed to deposit with the state librarian a record book of the society, dating back to 1806, and recording the meetings of the society from 1806 to 1862

In response to a communication from Dr McKay, of the State Department of Health, the society indorsed the work of the Division of Maternity, Infancy and Child Hygiene in holding periodic clinics throughout the county for preschool children

Adjourned for lunch

The meeting resumed after an excellent luncheon, with President-elect Noerling presiding, listened to an interesting address by President Nichols

Dr Andrew MacFarlane, of Albany, outlined the program of the State Society relative to Post Graduate Medical Education After considerable favorable discussion the Society decided to adopt the suggestions of Dr MacFarlane, and the secretary was instructed to communicate with Dr Gordon relative to starting a course of lectures in the near future

The officers of the Society were directed to arrange for a joint meeting of Albany, Berkshire and Columbia counties next year

The following committees were appointed by President-elect Noerling for the coming year

Legislative Maxon, Garnsey, Van Hoesen, Oliver and Collins

Public Health and Post-Graduate Medical Education Whitbeck, Mambert, Nichols, Diefendorf and Harris

Dr Frank Overton, Executive Editor of the State Journal of Medicine, made a plea that the county secretaries should send accounts of their society meetings to the State Journal, and also send the accounts to their local newspapers, for the activities of the doctors were of great civic interest

Dr Joseph S Lawrence, Executive Officer of the State Society, described the opportunities of the District Branches in coordinating the work of the county societies

Dr Herman G Weiskotten, Dean of the Syracuse Medical School and member of the Committee on Public Health and Medical Education, described the plan for graduate education that was proposed by the State Society

The following scientific program was carried out

"Diagnosis of Cancer of the Stomach with Special Reference to Acid Values," Dr I Harris Levy, Syracuse

"Surgical Procedures in Acute Perforation of the Stomach," Dr Gilbert D Gregor, Watertown

"Relief Measures During Labor," Dr Henry W Shoenek, Syracuse

The following officers were elected for two years President, Dr Charles D Post, Syracuse, First Vice President, Dr Page E Thornhill, Watertown, Second Vice President, Dr Augustus B Santry, Little Falls, Secretary, Dr William J McNerney, Saratoga, Treasurer, Dr Frank E Fox, Fulton

### THE EIGHTH DISTRICT BRANCH

Every District Branch meeting has a character of its own Dr Harry R Trick, President of the Eighth District Branch, carried out the excellent idea of devoting a morning session of his meeting to a discussion of the activities of the State Medical Society, the afternoon to a scientific program, and the evening to a social dinner and a semi-popular meeting with the exhibition of moving pictures and lantern slides The meeting was held on Wednesday, October 7th, in the Buffalo City Hospital, with about one hundred members present

Dr N B Van Etten, President of the Medical Society of the State of New York, described the activities and aspirations of the Society He said that the policies of the Society are in a state of rapid evolution, and that two important questions which are coming up this year are a novel medical practice act, and a more comprehensive system of defense against malpractice suits He told of the immense amount of detailed investigation and planning which had been done by the leaders during the past summer, and of their efforts to keep the members informed through the Journal, addresses and conversations

Dr Daniel S Dougherty, secretary of the State Society, gave a practical talk on the work of the secretaries of the societies of both the State and the counties It is the work of the secretary to be familiar with every phase of the work of the Society, and to see that the activities are conducted in an orderly way and through regular channels Dr Dougherty spoke of the need of harmony, toleration, and standardization in the societies and especially in the State organization with its augmented income and its increased number of active workers on its various committees

Dr W W Britt of Tonawanda, Secretary of the Eighth District Branch and Chairman of the Committee on Economics of the State Medical

Society, told about the plans of the Committee He said that the Committee had sent a questionnaire to the Presidents of all the county medical societies, asking what subjects they would recommend for consideration Nursing was the first choice, but since that subject is being handled by a special committee, Dr Britt's Committee would emphasize the second subject that was to be recommended—that of periodic health examinations

Dr Britt said that the fundamental need in the promotion of health examinations was a standard form for making and recording the examinations He exhibited various forms and also samples of the literature sent out by the Metropolitan Life Insurance Company and other organizations that are interested in health examinations

The meeting of the Eighth District Branch voted to recommend that the Committee on Economics prepare an examination blank and submit it to the next house of delegates to be adopted as the standard form for the whole State

A novel feature of the meeting was an exhibition of pathological specimens and X-Ray photographs prepared by Dr W F Jacobs, pathologist for the City Hospital A number of these specimens and pictures were exhibited at the meeting of the Medical Society of the State of New York, at Syracuse last May The pathological specimens are preserved in their natural colors, and are sectioned or opened in order to bring out the points to be emphasized There were gall bladders with gall stones looking like ladies' purses full of pearls, hearts with areas of muscle degeneration, and coronary thrombi, gastric ulcers with thickened walls, and perforations, and colons with intussusception The specimens were prepared with special reference to their value in teaching students Dr Goodale,

# BOOK REVIEWS

**AN INTRODUCTION TO DERMATOLOGY** By SIR NORMAN WALKER. Eighth Edition. With ninety plates and eighty illustrations in the text. William Wood and Company, New York, 1925 Price, \$7.00

This book of slightly more than 350 pages is practically a reproduction of the lectures given by the author at the University of Edinburgh, and is, therefore, rather elementary in type as the title suggests

The introductory section deals with the structure and function of the skin, as well as general diagnosis and treatment of skin diseases. After this, instead of following the classification laid down by Hebra, the author has rearranged the text in a manner which seems easier to grasp. He considers first Anomalies of Sensation, next, Anomalies of Secretion, and then in Section 4 treats with the Inflammations, including toxic eruptions. These Inflammations have been subdivided into those of the Surface Epidermis, and of the Deep Epidermis. The section also includes the Infective Inflammations in which he combines both the bacterial and parasitic infections.

Beginning on page 161 he has devoted about ten pages of the text to giving the Distribution of the Commoner Forms in Dermatitis, not in tabulated form, but in an easy, descriptive style, with suggestions on treatment. This latter statement will also hold true in regard to his handling of the individual dermatoses throughout the text.

There are incorporated in the book eighty illustrations in black and white and ninety-two really excellent plates, all but a few of which are in colors. These colored plates practically constitute a skin clinic.

The book is of the type desired by students or physicians not too far advanced in the knowledge of Dermatology. The treatments advised are generally conservative. E. ALMORE GAUVAIN

**SURGICAL CLINICS OF NORTH AMERICA.** Volume 4, Number 5, October, 1924 (Portland-Seattle Number). Published every other month by the W. B. Saunders Company, Phila. and London. Per clinic year (6 issues), cloth, \$16.00 net, paper, \$12.00 net.

The surgeons of the North West are the contributors to this number. Not unlike the clinics in any other part of the country, we find here a great variety of most interesting clinical cases, and a display of the highest type of surgical skill.

HERMAN SHANN

**SURGICAL CLINICS OF NORTH AMERICA.** Volume 4, Number 6, December, 1924 (Lahey Clinic Number). Published every other month by the W. B. Saunders Co., Phila. and London. Per Clinic Year (6 issues) Cloth, \$16.00 net, paper, \$12.00 net.

This volume is designated as the Lahey Clinic Number. The bulk of the number is contributed by Dr. Lahey of Boston, who deals with all possible varieties of thyroid disease. Every aspect of thyroid disturbance is thoroughly discussed, and the indication for various operative procedures are given in detail. Excellent illustrations accompany the text. A number of articles are contributed by the co-workers of his clinic. HERMAN SHANN

**THE THEORY AND PRACTICE OF THE STEINACH OPERATION WITH A REPORT ON ONE HUNDRED CASES** By DR. PETER SCHMIDT (Berlin) and an Introduction to the English edition by J. JOHNSTON ABRAHAM, C.B.E., D.S.O., M.A., M.D., F.R.C.S. (Eng.) 12mo of 150 pages. London, William Heinemann, 1924. Cloth, 7s. 6d.

One reason for this book's favorable impression on the reviewer is because the sponsor in the introduction states the efficacy of the Steinach operation to be a moot question. This is refreshing after so many writers on the subject have insisted that the procedure is a cure-all and a never failing nonesuch.

In the introduction and in a general survey in Chapter I, the endocrinology of the sexual glands is described, along with brief mention of various writers and their accomplishments. Also there is a summary of experiments in castration, spaying, homoplastic and autoplasmic grafts, and masculinization and feminization results.

To one personally unacquainted with any patients who have undergone the procedure the benefits claimed, even in as modest a book as this, are a little startling. A few of the troubles disappearing after the Steinach operation are languor, backache, mental exhaustion, baldness, sight and hearing defects, impotency, hypochondria, loss of weight, cardiac insufficiency and arrhythmia, and certain urinary difficulties. One wonders why auto-rejuvenation is not seen after epididymitis either in old men or under-par younger men. Epididymitis of gonorrheal or other cause is not rare, and in some patients at least, complete obstruction must take place, but rejuvenation has never followed in the experience of this reviewer. Despite the propaganda in the subject of rejuvenation applicants for the operation are rare. The list of disorders that these patients suffer belong in the real of the internist rather than to the genito-urinary specialist.

The operation is simple and safe. We are apt to hear more on it from those interested in the general condition of the old than from those doing work only in limited fields.

This book is interesting and presents the subject in a good manner free from the usual blatant exaggerations. GRAY PHILLIPS

**ELEMENTARY MORPHOLOGY AND PHYSIOLOGY FOR MEDICAL STUDENTS.** A Guide for the First Year and a Stepping-stone to the Second. By J. H. WOODGER B.Sc. Octavo of 528 pages, illustrated. New York, Oxford University Press, American Branch, 1924. Cloth, \$4.20.

The author, in his work justifies its publication on the assumption that premedical education is inadequate. The book begins with a foreword to the student in which the author implores the student to observe for himself, to be individual, and not to be a follower.

The rest of the book is devoted to the subject in hand. It begins with animal organization, its physiology, tissue and the cell are discussed. - Animalculae of lowest form are investigated and gradually those of a higher scale.

The text contents are described clearly and concisely. The subject matter is treated accurately and interestingly. There is a short bibliography at the end with an excellent index.

One may say that it is a splendid book fulfilling the author's desire to depart from the usual and make the young premedical student an investigator. S. R. SLATER.

(Continued on adv page xxvii)

# THE DAILY PRESS

We have frequently discussed the use of the daily press in imparting medical instruction to the people. We have thought out loud and have expressed our opinions of the medical items that have appeared in the newspapers. Our attitude has been one of dissatisfaction.

We have had very little occasion to criticize the editors of the newspapers. The editors have nearly always printed what has been given to them, and have usually preserved the style of the items.

We have frequently realized the difficulty in finding in a news item that feature which makes it live news. An item must appeal to the particular paper. An epidemic in Buffalo does not excite the people of Montauk Point, and few people care whether or not a treater of horses is called by the title of doctor. We have pointed out that nearly all publicity is built around persons. Anything that affects a well-known person, or a considerable number of persons in a community, is live news.

We have also frequently suggested that doctors themselves have the power to secure the publication of almost any kind of medical information that they desire. They hold the key to medical publicity.

The publication of medical items in the newspapers is a duty for county medical societies to assume. A committee on medical publicity would be valuable in every county society.

A county society that adopts the plan of appointing a committee on publicity will probably have difficulty in securing the personnel to serve on the committee. Most doctors have an aversion to writing—why that is so, is incomprehensible. Are the high schools and colleges failing to teach their students to write? We believe so, but the supply of doctors during the next ten years will continue to be averse to writing. If we had our way, we would compel every medical student to devote one of his summer vacations to reporting for a newspaper. He would then know what constitutes medical news, and how to secure its publication in the newspapers. Yet in spite of all this every county society can find two or three doctors to serve on a publicity committee.

What would be the duties of a publicity committee? The committee would have an exceedingly broad field, but for a starter, we will suggest only one duty—that of giving news of the meetings of the county medical society to the local newspapers.

Every meeting of a county society has something of special interest to the people of the county. The scientific papers may not appeal to the public, but a doctor can make such an application if he does a little thinking. But nearly every society discusses something of great public interest—health examinations, a new medical practice act, pure milk supplies, a venereal disease clinic. These and dozens of other topics may be developed in the account of the meeting.

The names of the local men who attended the meeting are always available. Surely they are of as much importance as the names of the women who attended the card party of the village thimble club.

Another legislative program is about to be announced, and its success will depend largely upon popular support. Possibly the neglect of newspaper publicity in the past has been a great factor in the failure of the proposed medical practice laws. It is the duty of physicians to see that their local newspapers are supplied with local medical items that will influence the people to support the proposed act. Possibly the legislative committee could take charge of the medical publicity in the newspapers of the county, but a publicity committee should be appointed.

The pages of this JOURNAL will contain explanations of the Medical Practice Act and arguments for its passage. Points that are brought up against the bill will be discussed and answered, and the bill will be explained from every standpoint. All this material will be available for the committees of county societies to use in their publicity campaigns.

One of the most effective means of publicity for the Medical Practice Act will be to reprint extracts from the JOURNAL in the local newspapers. These extracts can be made into live news if their relation to the local doctors is brought out. The very fact that a local physician takes the trouble to go to a reporter or editor is evidence of a local interest which can be turned into news. Probably the editor will ask the doctor what the item has to do with the town in which the paper is printed? It is work of the doctor to discover the local application of the extract, and give it a human interest.

The daily newspapers are ready to assist the doctors in promoting a high standard of medical practice, the local doctors must tell their local editors how to render that assistance.

## RESULTS OF SURGICAL TREATMENT OF CANCER\*

BY G W CRILE, M D

CLEVELAND OHIO

WHATEVER the changing aspects of the cancer problem, as far as its etiology is concerned, as to its prognosis one fact remains unchanged, namely, that cure depends upon the early complete removal of the primary focus of the cancerous process. There is no problem, therefore, regarding the treatment of cancer, that is, as to whether or not the cancer should be removed, if its location is such that its removal is anatomically possible. There is, however, a divergence of opinion as to the method of removal, centering principally about the relative merits of surgery and of radiation therapy.

The increasing knowledge of the effects of radiation, in particular the recent advances in the application of deep X-ray therapy, have aroused widespread discussion as to the relative values of radiation and of surgery in the treatment of cancer wherever situated. The settlement of this problem must depend upon the careful sifting of the clinical data provided by the experience of surgeons and radiation therapists. It is only by a comparative study of the end-results of these different methods of treatment that a final decision can be reached as to the method of choice in the treatment of cancer of any organ or part.

Already such studies have led some of us to prefer radiation in the treatment of cancer in certain organs and tissues, although even in such cases we cannot consider our judgment as final, but hold ourselves in readiness to reverse our present practice if later evidence appears to contravert our present conclusions.

It has seemed best to me, therefore, in my presentation today, to offer the present opinion of my associates and myself regarding the preferred method of treatment of carcinoma of certain organs and tissues of the body as based upon our combined experience in 4,108 cases of cancer, among which 3,414 have been treated by

surgery or by radiation or by a combination of both.

*Cancer of the Skin*—For carcinoma of the skin radium therapy is usually the most efficient treatment except in the case of a pigmented mole which metastasizes early and should always be excised.

*Carcinoma of the Buccal Surfaces*—Carcinoma of the head and neck shows one great advantage over cancer of the other organs and tissues, namely, cancer of the jaw, tongue, cheek and lips is rarely disseminated to other parts of the organism. In a recent study of the literature pertaining to cancer of the head and neck we found that among 4,500 reported necropsies, in only 1 per cent were secondary foci found in distant organs or tissues. The collar of lymphatics about the neck forms an almost impassable barrier through which cancer rarely penetrates and every portion of this barrier is readily accessible to the surgeon. Within the lymphatic collar, however, metastases are rapidly disseminated, although cancer of each part of the head seems to follow a law of its own as far as its primary extension is concerned. This fact provides the key to the treatment of cancer of these parts, the prime requisite being the complete removal of the lymphatic glands which are related to the site of the cancerous growth.

*Early cancer of the mucous membrane of the gums or cheeks* does not demand excision of the glands. Good results in these cases are usually obtained by the use of the electric cautery. Radium therapy is the preferred method of treatment in early cases of *cancer of the lip*. In late cases the cancer should be excised by means of a V-shaped incision, the scar of which is no more noticeable than that produced by radium.

The most efficient method for destroying an early *cancer of the tongue* is electric coagulation or cauterization with the actual cautery. Radium would suffice to destroy the growth, but the radium burn is exceedingly painful.

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Syracuse May 12 1925

**PRACTICAL CLINICAL PSYCHIATRY FOR STUDENTS AND PRACTITIONERS** By EDWARD A. STRECKER, A.M., M.D., and FRANKLIN G. ERAUGH, A.B., M.D. Octavo, 375 pages, illustrated Philadelphia, P. Blakiston's Son and Co., 1925 Cloth, \$4.00

Although this book is written for practitioners and students of medicine, it contains much of interest to the laity, because of its most interesting contents and its simplicity of style, rendering it readily comprehensible to one unfamiliar with strictly technical terms. It might even be of value to the layman, from the fact that it is capable of erasing from the popular mind the idea that any one suffering from mental symptoms is immediately locked up, innumerable papers having been duly signed, and then forgotten. In the present day, such is far from the case. In this book we discover to what extent there have been accomplishments along these lines, and it seems the more remarkable, the institution of psychiatry as yet being very young. The chapters on "Methods of Examinations" and those on various types of psychoses are very interesting, and more and more do we feel, as we read on, what a delicate thing is this new science—thus dealing with mental phenomena. It is an excellent book for the student because the subject is so very clearly and carefully dealt with in its details and because it is explicit and interesting in examples.

F. C. E.

**GYNECOLOGY FOR NURSES** By M. J. SEIFERT, A.B., M.D., F.A.C.S., Attending Surgeon and Gynecologist, Columbus Hospital, Chicago. D. Appleton and Co., New York, 1925.

There is urgent need of a textbook of Gynecology for Nurses. The volume under review does not, however, fulfill all the requirements of a textbook for nurses, chiefly for the reason that it has too much information that is surgical and medical and not enough nursing.

The author has covered well the subject of gynecology and, best of all the practical side of the subject is excellently given. With few exceptions the opinions expressed are those of a general surgeon doing good gynecology. It would seem, however, that such a text would be better suited for medical students than for nurses for after all the nurse is to care for the case—doing what she can to make the patient comfortable. Diagnosis and therapeutics are strictly medical and not nursing problems.

H. B. MATTHEWS

**LECTURES ON GONORRHOEA IN WOMEN AND CHILDREN** By J. JOHNSTON ABRAHAM, C.B.E., D.S.O., M.A., M.D. F.R.C.S. 12mo of 142 pages, illustrations London, William Heinemann, 1924 Cloth, 7s. 6d.

In this book of 136 pages the author has given a brief description of the immediate and remote manifestations of gonorrhoea in women and children. The author claims that the subject of gonorrhoea in women is still strangely neglected in England and this fact is true as far as this country is concerned. He has therefore given in this book the methods of examination of a female patient with a history suggestive of a gonococcal infection, the symptoms usually complained of in this infection, and finally he has put forward certain lines of treatment for the early curable stages of the disease, which can be followed out successfully without any special apparatus beyond those found in every doctor's cabinet and without any skill beyond that possessed by the average practitioner.

It is a book that should be read by everyone who attempts to treat this neglected and difficult subject.

PHILIP GOLDFADER.

**MEDICINE. AN HISTORICAL OUTLINE.** By M. G. SEELIG, M.D. 12mo of 207 pages. Baltimore, Williams and Wilkins Co., 1925 Cloth, \$2.25.

This octavo of 207 pages, including an index, with 198 illustrations, is just what the title indicates, a historical outline of medicine, or, perhaps better, a flying sketch of the important periods of medical history. There is a somewhat ornate foreword by Fielding Garrison, and the author of the book gives sufficient warrant for writing it in his preface. The context covers eight lectures, including primitive and early Oriental medicine, the Greek and Graeco-Roman era, the Middle Ages, the sixteenth, seventeenth, eighteenth and nineteenth centuries.

Prof. Seelig has woven a story of medical history which ingeniously combines chronology with theory and the great personalities associated with them in a manner calculated to both interest and stimulate students of medicine in high degree. He shows evident grasp of the subject, and the facts presented make clear the interdependence of the true growth of medical science and our increasing knowledge of the sciences in general, together with the steady improvement of instruments of precision.

Withal there is a human touch in the book, which vivifies and lends a charm to it, making it read almost like a novel. Medical students and practitioners alike should possess, read and re-read this little book, until it becomes an integer of their gray matter. In so doing they will be led to further study of a subject which can only lead to a broader vision of and respect for the profession of their choice.

J. M. VAN COTT

**PREPARATION OF SCIENTIFIC AND TECHNICAL PAPERS** By SAM F. TRELEASE and EMMA SAREPTA VULE. 12mo of 113 pages. Baltimore, Williams and Wilkins Co., 1925 Cloth, \$1.50.

This book contains many technical suggestions of value to the scientific writer. The list of medical periodicals quoted is poorly chosen and inadequate. This book may prove helpful to scientific writers, but we believe it does not cover the subject of medical writing as completely as it should. This may not have been intended by the writers.

FREDERIC DAMRAU

**FROM INFANCY TO CHILDHOOD. The Child from Two to Six Years** By RICHARD M. SMITH, M.D., Assistant Professor, Child Hygiene, Harvard University. The Atlantic Monthly Press, Boston, 1925.

Chapter I gives timely advice to parents, urging periodic examination of children between two and six years.

Under Diseases, the care of "Croup" may give a false sense of security to an inexperienced mother, if she understands that "Syr. Ipecac in 10-drop doses" will cure croup, "which may recur for two or three nights." The book does not warn the reader against diphtheritic croup. This treacherous disease may be mistaken for the harmless catarrhal laryngitis to which the author apparently has reference. One must realize the possible consequences from the delay to administer antitoxin, should the case prove to be diphtheria. Indeed it is very unsafe to leave the differential diagnosis of croup to any lay person, when one realizes that it not infrequently taxes the ingenuity of an experienced physician.

In discussing "Swallowing of Foreign Bodies" the author misses an opportunity by not warning against the things that make it possible for any baby to either swallow or aspirate a foreign body. Certainly this accident is 100 per cent avoidable. Not a word is uttered against this carelessness on the part of parents or nurses.

Books of this class have no place in the modern nursery unless they discuss the prevention and avoidance of avoidable accidents and preventable diseases.

The mother or nurse may read this book with some benefit.

HARRY APPEL

month in 6, and yet in many of these cases emaciation and exhaustion as a result of dysphagia were already marked

*Carcinoma of the Breast*—Our total series of 1300 operations on the breast includes 752 operations for malignant tumors. We have follow-up data in 530 cases in which a radical operation was performed, of these 145 have lived for five years or more. Of these 530 cases, 356 were treated by surgery alone, with 128 five-year survivals, 174 by surgery plus radiation, with 17 five-year survivals.

In this discussion I shall summarize our present point of view regarding the treatment of cancer of the breast by the brief statement that the early radical operation is the only method to be employed, and that excepting in manifestly inoperable cases the patient should be given the benefit of the doubt and radical operation performed.

As to the role of radiation there is not a sufficient uniformity in the reported results to form any final basis for judgment. It is certain that radiation by itself alone cannot be compared with surgery, and our own statistics have definitely proven that intensive post-operative radiation is distinctly contraindicated.

*Carcinoma of the Stomach*—As in the case of cancer of the esophagus, a cancer of the stomach is characterized by a rapidity of growth, and an extent of lymphatic involvement so that the "dead line" of inoperability is reached very early in its progress. A period of a few weeks may be sufficient to carry the patient from an operable to a completely inoperable condition and consequently in the majority of cases the patient comes to operation too late for possible cure. When operable, as in the case of carcinoma elsewhere, resection with the widest possible excision of the growth is the indicated procedure. Blood transfusion, saline injections, nitrous oxid analgesia, the application of hot packs and divided operation may suffice, however, to carry through many patients in whom the prognosis appears to be hopeless, but in whom the anatomical possibilities of operation have not been passed.

In many cases the diagnosis of cancer is made when the lesion is an ulcer. The relation between ulcer and cancer of the stomach remains to be finally established, but it is probable that cancer is preceded by ulcer in not more than 10 per cent of the cases. Even this low percentage is sufficient, however, to warrant the removal of the ulcer by operation.

Our series includes 393 cases of carcinoma of the stomach among which 310 have been operated upon—3 per cent of our total number,

1009—of operations on the stomach. Follow-up data are available in 130 of these cases among which 11 have passed the five-year period. Of these 130 cases resections were made in 23 with one five-year survival, gastroenterostomy in 61, with 6 five-year survivals, exploratory in 43 with 3 five-year survivals, and radiation therapy only was done in three with one five-year survival. The question may well be raised regarding the pathological diagnosis in the last cited groups. We can say only that the clinical signs and the exploratory operations gave every evidence of an inoperable condition in each.

*Carcinoma of the Gall Bladder*—Carcinoma of the gall bladder is usually associated with cholecystitis and consequently in most cases the disease has extended into the liver and adjacent deep structures before the malignant condition is recognized. For this reason the prognosis is extremely unfavorable, even after a radical operation. Our records include 54 cases of carcinoma of the gall bladder, among which 43 were operated upon. Among these we have no records of any five-year survivals.

*Carcinoma of the Intestines, Sigmoid and Rectum*—Radiation is of little avail in the treatment of lesions of the abdominal viscera. For cancer of the small intestine—which is of very rare occurrence, of the cecum, the transverse colon, the descending colon, or the sigmoid, surgical treatment is indicated. The operative management as in cases of carcinoma of the stomach being directed to the utmost conservation of the resources of the patient, and as in the former case, transfusion, saline infusions, divided operation and nitrous oxid analgesia, may suffice to carry through the apparently hopeless patient.

For the treatment of cancer of the rectum on the other hand, the combination of radium with deep X-ray therapy promises to supplant surgery, for the rectum is readily accessible for the implantation of radium and many portals of entry are available for deep X-rays.

*Carcinoma of the Uterus*—I doubt whether a wider diversity of opinion regarding treatment exists in any field of surgery than in the treatment of carcinoma of the uterus. Up until within the last year or two this could be said regarding carcinoma of the cervix also. During the past few years, however, the accumulation of statistics in regard to the value of radiation therapy of carcinoma of the cervix has developed to such a degree that its pre-eminent value appears to be established. In the case of carcinoma of the cervix as in the case of carcinoma of the Rectum, we are turning over all of our cases to radium and deep X-ray therapy, and for the same reason, that is, there

Cancer of the tongue calls for the complete removal of the glands of the neck on both sides if the lesion extends toward the midline, while cancers of the buccal surface, which metastasize rarely and usually only on the side of the lesion, demand a less radical operation. In advanced cases, however, no matter where the primary lesion, a wide regional block excision is demanded. Since we adopted this plan, which involves excision of the sterno-mastoid and of both jugular veins, together with the larynx, we have rarely missed securing a permanent cure with any case which has not progressed beyond the lymphatic plains of the neck.

Our statistics include 107 cases of carcinoma of the buccal surfaces, of which 75 have been treated. We have follow-up data regarding 24 of these cases, in which a radical operation was performed, of these seven have lived for five years or more.

*Carcinoma of the Larynx*—Intrinsic carcinoma of the larynx is even more protected from metastases than carcinoma of the group of organs which we have just discussed. Surgical treatment—laryngectomy—is definitely indicated. Although there are a few who advocate the use of radium in early cases, the general trend of opinion is adverse to its use. The only argument in favor of radium as against surgery would appear to be escape from mutilation, but the mutilation is so slight and the patient so soon becomes adapted to the loss of voice that these do not seem to be valid arguments in favor of radium, whereas the practical certainty of cure provided the carcinoma is entirely intrinsic should lead one unquestionably to accept the dictum that surgery is the one method in these cases.

The postoperative application of the X-ray, however, is of value in that it may serve to check any extension of the growth providing some extrinsic focus may exist.

Extrinsic cancer of the larynx, however, presents a different problem, and surgical treatment in these cases should always include a block dissection of the gland-bearing area. In inoperable cases of extrinsic cancer of the larynx in which only tracheotomy can be attempted, radium is of value as a palliative measure. On the other hand, it should be borne in mind that extrinsic cancer of the larynx is even more accessible than cancer of the tonsil or cancer of the pharynx, and my own experience has included cases in which an apparently hopeless extension of the growth has been followed by complete recovery. In one case the growth involved not only the larynx but in addition, all of the tissues between the juncture of the posterior and the middle third of the tongue were involved and removed as well as the upper region of the

trachea and the upper end of the esophagus. This patient has lived without recurrence for six years since the second operation.

Our series includes 79 cases of carcinoma of the larynx, among which 64 were operated upon. We have follow-up data regarding 26 of these patients, of whom 2 have survived for more than the five-year period.

*Carcinoma of the Thyroid*—In our total series of 6,427 thyroidectomies there has been a carcinoma of the gland in 139 cases. It is significant to note that in about 95 per cent of these cases the carcinoma was due to a degeneration of a foetal adenoma, and inversely that approximately 10 per cent of all foetal adenomata seen at operation are cancerous. For these reasons I believe that a foetal adenoma should always be removed. Iodin has no effect upon a foetal adenoma, and moreover in these cases iodine often produces myocarditis and hyperthyroidism. A malignant foetal adenoma is always removed if possible, otherwise it is treated with radium. A foetal adenoma is the easiest of all types of goiter to remove. Simple adenoma is generally multiple, foetal adenoma is usually a well defined tumor and is present on one side only. A patient with an inoperable carcinoma of the thyroid gland will live without radiation for about one year. As for the length of life with radiation, there is no basis upon which to found a final judgment. Sometimes the mass disappears, in other cases, radiation does not seem to do any good. In cases in which the patient is suffering from obstruction and resultant partial asphyxiation, a decompression operation will serve to give temporary relief, the operation being followed by radiation. In such cases an acute myxedema may develop but this myxedema is readily met by the administration of thyroid extract.

In our series of cases of carcinoma of the thyroid which received surgical treatment we have follow-up data regarding 53 patients of whom 15 have lived for more than five years since operation.

*Carcinoma of the Esophagus*—Carcinoma of the esophagus, in contradistinction to carcinoma of the larynx, is one of the most hopeless among malignant conditions. The cases usually are presented too late for any surgical procedure to be of value. Radium and deep X-ray therapy, however, present some basis for hope, especially in the earlier cases, although the progress of the disease in these cases is always exceedingly rapid. Thus in the records of the Cleveland clinic among 31 cases of carcinoma of the esophagus, the duration of symptoms had been less than 10 months in all, but 5 cases, less than 6 months in 18, less than 3 months in 11, less than 1

persons who become afflicted with cancer will die from this disease. Of course, this includes all the types of malignancy. It is thus quite evident that our present methods of treatment are not all that could be desired. You have just listened to the foremost authorities upon the present status of treatment by the best methods available at this time. It is but natural that they would stress the possibilities in their respective lines—I believe it would not be amiss if I were to call your attention to the limitations.

**Surgery**—Surgery is definitely limited. In the first place, the question of operability is always to be considered, and even this varies, according to the skill and judgment of the surgeon. Thus, we can see that cancer, in its relation to surgery, may be divided into two great groups, *viz*, first, those cases which are operable, and second, those which are not, either because of the extent of the lesion or for any other reason. Experience shows us that in certain types of cancer, a very large number are past the operative stage when they present themselves to the surgeon for treatment.

It is clear, then, what the limitations of surgery are. Theoretically, every case in group one should be cured if the patient has the services of a competent surgeon, but this ideal state of affairs does not exist, as is proven by surgical statistics. I believe that two factors are largely accountable for our present results. First, either the surgeon fails to differentiate between the mechanical operability and the therapeutic operability, or secondly, at the time of operation, imperceptible metastatic cells are present. So we have added to the group of inoperable cases, the recurrent ones.

**Radiation**—Personally, I do not accept any difference between the mechanism which brings about the results obtained in the use of radium, from those obtained from X-rays. It resolves itself into the question of either the availability or the most convenient method of application. So these two agents may be considered together, under the caption, "Radiation Therapy."

It was thought, when radiation was first introduced as a method of treatment for cancer, that the inoperable and recurrent cases would be taken care of, but it soon became apparent that this method of treatment had its limitations. The majority of inoperable and recurrent cases did not respond to radiation treatment as it had been hoped they would. However, there is thus much to be said for radiation—by its application a malignant neoplasm may be made to disappear. We know that it has the *potentiality* of destroying or nullifying cancer cells. Unfortunately, we are unable, as yet, to explain the mechanism of this action. Is it a caustic action, or is it a specific one, either on the cancer cells themselves, or on their environment? Up to the present time,

we have been working with radiation in a purely empirical way, obtaining results without a definite knowledge of its mode of action. Should it transpire that this agent has a specific action on cancer cells, the outlook for future results, by using this method of treatment, is very bright.

A lead in this direction that is promising is being followed at our Institute. It is a well-known fact that the presence of oxygen is necessary for the growth energy of normal cells, but it has been found that cancer cells will multiply in the absence of this element. The energy is derived from the fermentation of sugars. The ability to convert sugar into lactic acid seems to be a property of the cancer cell. That this occurs has been demonstrated in our laboratory by our biological chemist, Dr. Cori, both on tumor-bearing animals and on humans. We are working, at present, to determine if radiation has any action upon this particular process.

I do not believe that comparisons should be made between the relative value of surgery and radiation in the treatment of cancer. The possibilities and limitations of surgery should be recognized and applied to appropriate cases. Radiation cannot be finally judged until we learn definitely the exact mechanism of its action.

I would, with your permission, change the title of my paper to the following one: "Present Status of the Treatment of the Cancer Problem." Aside from the question of etiology, the most vital cancer problem today is this—what can we do to decrease the mortality of the 70 per cent. It may be conceded, that the majority of cases of localized cancer can be cured with either surgery, radiation or diathermy. Then the apparent answer to this problem is, to get them in the early stages. Much can be done and is being done by the education of the laity. We have a valuable agent in the American Society for the Control of Cancer to help us disseminate knowledge, which is valuable to persons who have early or precancerous lesions. We should stand firmly behind this society and lend it our aid.

But the responsibility is not entirely limited to the laity, for the records of some of the cases which appear at our Institute, show distinct evidence of procrastination and lack of a complete examination, upon the part of the physicians who were consulted first. This is particularly true of rectal examinations.

It seems to me that if the early diagnosis of cancer were given as much prominence on the curriculum of our medical colleges as is given to appendicitis and tuberculosis, we would materially improve our statistics.

Another more difficult problem, which as yet we have not solved, is to obtain some dependable method for the early diagnosis of deep-seated cancer. The need for this stands out in regard to gastric malignancy, which, as you know, shows

are so many portals of entry for the X-rays and the cervix is so readily accessible for radium implantation that the entire invaded region may be reached without endangering the abdominal viscera. As for carcinoma of the fundus, however, we still advocate vaginal hysterectomy in all cases.

**Cancer Within the Genito-Urinary Tract**—In general, reliance must still be placed upon surgery for the treatment of carcinoma of the genito-urinary organs. In some cases carcinoma of the kidneys in children will be reduced by deep X-ray therapy, but the radiation must be followed later by surgery. In the case of deep seated bladder tumors, radium has seemed to prevail in certain cases, but here also the results are still too uncertain for radiation to be used routinely. Postoperative radiation is employed in many cases, but more because it is hoped that it may be of avail than because of any definite results.

In conclusion, according to our experience our present judgment regarding the treatment of cancer of the organs discussed in this paper may be summarized as follows:

1 *Skin*—Radiation, except in cases of pigmented moles which should be excised.

2 *Buccal Surfaces*—Mucous membranes of mouth—excision. Early cancer of tongue, electric coagulation or actual cautery, early cancer of lip, radium, late cancer of tongue or lip, excision plus block dissection of glands.

3 *Larynx*—For intrinsic carcinoma, laryngectomy plus postoperative radiation, for extrinsic carcinoma, block dissection plus radiation if operable, tracheotomy plus radiation if inoperable.

4 *Thyroid*—Thyroidectomy plus radiation if operable, decompression plus radiation if inoperable, prevention by excision of foetal adenomata.

5 *Esophagus*—Gastrostomy for feeding plus radiation.

6 *Breast*—Radical operation. The value of radiation is still *sub judice*.

7 *Stomach*—Resection if operable, gastroenterostomy if inoperable.

8 *Intestines and Sigmoid*—Colostomy plus radical operation if operable, colostomy plus radiation if inoperable.

9 *Rectum*—Colostomy plus radiation.

10 *Uterus*—For fundus, radical operation, for cervix, radiation.

11 *Genito-urinary Organs*—Operation plus post-operative radiation in selected cases.

#### RESULTS OF SURGICAL TREATMENT

	Total Cases	Treated by all methods	Heard from	Survival Period Five years or over

## THE PRESENT STATUS OF THE TREATMENT OF CANCER\*

BY BURTON T. SIMPSON, M.D.

BUFFALO, N. Y.

### Introduction

WHEN we consider that the only reliable methods available today for the treatment of cancer are surgery, radium, X-ray and diathermy, we cannot help but feel, after listening to the excellent presentations covering these methods of treatment, that there is very little which has not been thoroughly covered by the previous speakers. I think you will also agree that there is not much left for me to discuss. I might, however, take up the question of diathermy, had not Dr. Wyeth handled this subject so well, last year, at the Rochester meeting. It

was my understanding, when I was invited by your chairman to take part in the symposium, that I was to open the discussion of the papers given. But when I received the program I found, much to my surprise, that a subject had been assigned to me, and I could not help but feel that, undoubtedly, the three preceding speakers would be sure to cover all that is to be said concerning the treatment of cancer.

However, as the honor has been conferred upon me to read a paper, I will try to avoid a repetition of the facts already told you, and will endeavor to bring to your attention some information which may be of interest to you.

Statistics show that 70 out of every hundred

## X-RAY IN CANCER THERAPY \*

BY BERNARD F SCHREINER, M D, F.A.C.S

BUFFALO, N Y

**F**OLLOWING the discovery of X-rays in 1895 by Professor Roentgen, Herbert Jackson constructed an X-ray tube with a focusing spot for the cathode stream, using platinum for the anode. Numerous experimenters devised ways and means for utilizing these rays for photographing bones. It was during this period that the observation of the effect on skin was noted, namely, dermatitis and sometimes severe ulceration, which was the common X-ray burn in the early work. Shortly after the discovery of X-rays by Roentgen, Schiff and Freund making use of this information, suggested the value of X-rays in the treatment of disease. From 1896 to 1906, great optimism prevailed and it was during this era that physicians subjected their patients as well as themselves to the deleterious effects of X-rays, which for a time caused this valuable means of combating malignant disease to fall into disrepute. From 1906 to 1912 a few investigators like Pusey, Pancoast, Stelwagen, Pfahler, and others in this country, and Schiff, Freund and Holzkecht in Europe, persisted in their efforts at perfecting technique which would prove of value.

During a period from 1908 to 1912 an interrupterless transformer was given to us by Snook, while others were making improvements in the old gas tubes. In 1914, Dr Coolidge, of the General Electric Company, perfected the Coolidge tube. These contributions to science did as much as any other discovery in the development of X-ray therapeutics. With the improvement in the apparatus and tubes, physical and biological measurements were introduced by various physicists and Roentgenologists, among whom were Kroenig, Friederich, Duane, Dessauer, Stenström, Holfelder, Sabouran, Holzkecht and Kienbock, so that the treatment of cancer has become more or less standardized in this way.

Our present use of X-rays in combating cancer may be divided into three methods

1 Unfiltered X-rays

2 Low voltage X-rays with aluminum, zinc or copper filters

3 High voltage X-rays with heavy filtration

Our methods of treatment must necessarily be limited according to the biological effects as well as the physical measurements. In the use of unfiltered X-rays in the beginning, they were used empirically, the dose depending on the erythema of the skin. At the Institute unfiltered X-rays<sup>1</sup> were used after a period of empiricism, followed by physical measurements which were

made by means of photographic paper calibrated on the biologic effect as expressed by erythema. It is necessary to standardize the conditions under which X-rays are given, namely, as to voltage used, milliamperage, distance, filtration, time and size of fields. Unfiltered X-rays are of value in the treatment of all superficial lesions, such as basal cell epitheliomata,<sup>2</sup> pigmented naevi, epithelioma of the lip,<sup>3</sup> and penis.<sup>4</sup> Basal cell epithelioma can be healed in 95 per cent of the cases as they present themselves at the Institute by means of a full erythema dose of unfiltered X-rays. One or two treatments usually suffice. In the treatment of pearl forming or prickle cell epithelioma, such as occur on the lip, skin and penis, we have had a primary healing in 75 per cent of the primary cases, of which 50 per cent are apparently permanent. It is often necessary to administer from two to three times the erythema dose on a lesion, being careful to block off the surrounding tissue (with leaded rubber) depending on the thickness of the lesion.

Low voltage X-ray, 140,000 volts, using 2½ mm aluminum or 25 mm copper, at a distance of 20 to 30 cm is of value in attacking lesions situated not more than 3 cm below the skin. The use of low voltage X-rays at the Institute is much curtailed in view of the great flexibility of the high voltage X-rays as to time and distance required for treatment. Low voltage X-rays with aluminum filter or copper filter can be used in the prophylactic treatment of breast cancer following operation as well as in the routine treatment of fibroids providing the patient is not too thick.

The use of high voltage X-rays has been standardized at the Institute and is very flexible, thereby conserving a great deal of time and delivering as much as 50 per cent, 10 cm below the skin. This apparatus is using 200,000 volts, 30 milliamperes, 5 mm copper, distance varying from 30 to 80 cm, size of field from 6 x 8 cm up to 20 x 20 cm, time factor varying accordingly, 6 minutes up to 30 minutes for various distances.

In the treatment of cancer by X-rays, three important factors suggest themselves

1 Is it possible to annihilate a cancer cell or a malignant tumor cell by one large dose of radiation?

2 Is it more efficacious to divide a known quantity of X-rays over a given period of time in the hope that cells which are in various stages of mitosis can be destroyed?

3 Is the effect of X-rays in the healing of cancer due entirely to action on malignant tumor

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 12 1925

the highest mortality of all types of cancer. An immense amount of research has been done on this aspect of the problem. In a recent review of this work, made at our Institute, we analyzed and checked up over fifteen methods, which had been brought forward in more recent years, for the early diagnosis of cancer. It was found that none of them was thoroughly dependable. However, every effort is being made to find such a test, by nearly all cancer research laboratories throughout the world.

Even if we educate the laity to seek advice early, stimulate the internist to be more keen in his examination, we will always have with us those cases which are insidious and impossible of early diagnosis, and also the recurrent cases, which are due to indiscernible metastases.

Today, these cases are one of our urgent problems. How are they handled? Either they are sent to the radiologist to see what he can do, or morphine is prescribed, to make the patient as comfortable as possible until he dies. It is my opinion that, at the present time, it is unwise to treat advanced cases with radiation. It is sure to cause the patient increased suffering, and the possibility of a cure is almost nil. Also, experiments carried on in our laboratory with primary mouse tumors, show definitely that morphine decreases the resistance of the animal against its tumor growth. This, too, has been borne out by our clinical experiences.

I believe it is a mistake to abandon the inoperable cancer patient. He should have the same careful medical care that any other person with a chronic disease gets. Not only should attention be paid to elimination, diet, tonics, local treatment, etc., but stress should be laid upon the psychic management of the patient. In this way much suffering could be obviated and life prolonged.

The ideal treatment of cancer would be the intravenous administration of some substance which would be inimical to cancer cells and harmless to normal ones. That there is some possibility of a hope for such an agent is shown by the work of Wassermann. He found that a combination of selenium and eosin, introduced into the circulation of tumor-bearing animals, would cause the tumors to disappear. However, the difference between the fatal dose for the tumor cells and the normal cells was so slight, that for every mouse that was cured, nine were killed. Therefore, it is clear that this method could not be put in practical application. Nevertheless we are continuously working along these lines, trying out empirically organic compounds, aniline dyes, hormones, etc.

Before closing, I wish to call your attention to one phase of the cancer problem, which is of much importance, but which has seemingly been neglected. That is, the danger of palpating breast tumors. This, I think, is the chief factor in the unfavorable results which we obtain in the surgical treatment of cancer of the breast.

Mortality from cancer of the breast is second only to that of cancer of the uterus in the female. Considering the following facts, it ought to be one of the most favorable types of cancer for cure. For it is discernible early, easily accessible and susceptible to complete removal. Why, then, is the mortality from this type of malignancy so high? The answer is, that premature metastases have been established by massage.

Experimentally, in breast cancer of white mice, we can produce at will early metastases by massaging the tumor. Strains which normally do not show metastases until the sixth or eighth month, can be made to have them at the third month by manipulating the tumor frequently for a few days.

Let us take a hypothetical example. A woman discovers a "lump" in her breast. She has heard that this is a very serious thing and naturally becomes alarmed. She continually feels of this lump to make sure that it is there. Often she asks her husband, or one of her friends, to feel of it. This, of course, amounts to massage. After a time, she goes to her physician, who makes a "thorough examination." Certainly, if he does his duty, he advises immediate consultation of a surgeon, who, in turn, adds his palpation to the tumor. Thus we see that in the natural history of most breast tumors, there is considerable handling before the lesion is removed, and often indiscernible metastases have been established, although the patient is considered a favorable early case.

It would seem to me, that there should be instituted a widespread educational attack upon this aspect of breast cancer. The danger of manipulation should be brought home, not only to the laity, but also to the medical profession. It should be impressed upon the latter that it is not always necessary to make a definite clinical diagnosis of cancer. The presence of a tumor in the breast, whether it be malignant or not, is sufficient evidence to justify an immediate operation.

It is evident that the unfavorable results obtained in the treatment of cancer of the breast are due to premature metastases. These, most probably, are brought about by excessive handling of the tumor by the patient, and very often by a too vigorous examination by the physician.

constant a degree of saturation over a period of ten or more days, hoping thereby to produce better results in the various types of cancer we are called upon to treat. That this coincides, although somewhat empirically, with the knowledge that we are obtaining by persistent investigation, is borne out clinically and by observations made by Murphy and myself

In April, 1918, a case of metastatic carcinoma of the breast, which was considered hopeless, was subjected to the removal of a metastatic nodule, with the patient's consent. This nodule was divided into three portions, the idea being to ascertain, if possible, the amount of radiation necessary to destroy tumor cells so that they could not be implanted. One part was subjected to a full erythema dose of unfiltered X-rays. A small incision was made in the skin over the abdomen and the tumor tissue inserted subcutaneously. One piece was used for control and was buried in another place beneath the skin. A third piece of tumor which was not radiated was implanted underneath the skin in an area which had been subjected to a full erythema dose of unfiltered rays. The result was that the control piece of tumor grew. The tissue which was radiated and then inserted in the body did not grow, nor did the tissue which was not radiated but planted in the radiated site grow. The significance of this observation, although only on one case, was not impressive enough at the time, so was not followed up. Little was thought about this until Murphy's work on animals which showed that transplanted tumor in radiated sites did not grow. This position brought us to the realization that the beneficial results from X-rays in the treatment of cancer cannot alone be attributed to the effect of the rays on the tumor cells themselves, but rather as a combined effect in which there must be a biological reaction in the normal tissues as well as the cancer cells. These facts have impressed themselves on us so that our investigations are now being pushed along the lines of trying to maintain such a state of affairs as exists in a given erythema dose by trying to prolong these effects by division of a known quantity of X-rays over a given period of time. This seems promising although we are not yet ready to set the exact time interval between the division of the dose and whether or not the end results will be more gratifying.

## Conclusions

I We believe that the subject of X-radiation is in its infancy and leaves much work to be done before drawing absolute conclusions as to the merits of this form of cancer therapy

II These investigations should be carried on by competent clinicians in conjunction with physicists so that careful data can be accumulated on these points

III While many people are inclined to be pessimistic in so far as the value of X-rays in the treatment of malignant disease is concerned, we have ample proof that no other known form of therapy can accomplish in certain cases what radiation can

IV Radium and X-ray therapy have a fundamental principle in common, that it is necessary to think in the same terms no matter whether one agent or the other is used, or a combination of the methods

cells or the reaction of normal tissues in overcoming the diseased process, or both?

During the period of 1914 to 1922, there were many opinions held by numerous investigators as to the possibility of eradicating cancer tissue by the so-called massive doses. Much was said and written, especially by the German school, as to the annihilation of malignant disease by one massive dose which, as experience has shown, has proven a great disappointment in many forms of malignant disease, notably breast cancer. It was proposed after careful observation that certain types of tissue were highly sensitive to radiation, whether X-rays or radium (Regaud). From this was promulgated the so-called cancer dose. We all know that certain cells in the sexual organs, ovary and testicle, are destroyed by about 35 per cent of the so-called erythema dose. Other tissues, such as lymphoid tissue, succumb to 60 to 70 per cent of the erythema dose. Basal cell epitheliomata heal with approximately a full erythema dose, 100 per cent. We believe pearl forming epitheliomata require a little more radiation, at least 120 per cent. Carcinoma cells have been put down by various observers as 110-130 per cent, sarcomas, spindle cell, giant cell, ranging from 110-140 per cent of the skin dose, while certain types of myxosarcoma require even more, 150 per cent (?).

High voltage X-rays, as ordinarily employed, give one an opportunity of delivering from 24 per cent to 50 per cent of the skin erythema dose at 10 cm depth by adjusting the size of the field to various distances with a variation of the time factor. In this way one is enabled by one or more fields to administer doses up to 120 or even 150 per cent beneath the skin, depending on the portals of entry and area of the body to be treated. Along these lines have been developed extreme variations in methods of technique which have resulted in some improvement of the results in the treatment of cancer, but have left much to be desired. The idea that prevailed in this sort of treatment was to deliver one massive or so-called "knock-out" dose to the cancer, but it was soon discovered that unfortunately the effect on the organism was profound. There were many untoward symptoms<sup>3</sup> which denoted extreme degrees of disturbance of the metabolism, patients often succumbing to toxemias a few days to a few weeks after radiation. After a short time it was plainly seen that this method of radiating cancer subjects was doomed to failure as the treatment was as bad, if not worse, than the disease.

About three years ago, Wintz, the German investigator, called our attention to the importance of the amount of radiation absorbed during a given treatment. At this time Dr Karl Stenstrom, the physicist at our Institute, proposed a unit of body dose,<sup>4</sup> the following factors being

employed the amount of radiation which is absorbed in a field 10 x 10 cm x 5 cm thick from an erythema dose. This was designated as our standard and called 100 AX. All radiations from that time on were calculated as to the amount of radiation absorbed during a given treatment. This unit of body dose was adjusted to the weight of the patient with the result that we have learned the number of AX units per pound of body weight beyond which it is dangerous to push any further radiation, 15 AX on breast and chest cases and not higher than 20 AX per pound body weight on abdominal cases. From that time on we noticed a gradual decrease in the amount of sickness and depression following the X-ray treatments and apparently as good if not better results from the standpoint of the tumor. With these factors in mind, there developed a method called three-field arrangement for attacking tumors 3 to 5 cm below the skin. This enables one to deliver 120 per cent or even more of the skin dose into the tumor without injury to the skin with a corresponding low body dose. The application of this method has also proven useful in tumors of extremities and stomach cancer. The publication of this method will appear shortly by Drs Stenstrom and Mattick.<sup>5</sup>

Keeping the problem of body dose before us, a large number of our cases have been treated by combined methods. For example, in cases of cancer of the uterus,<sup>7</sup> rectum, naso-pharynx, pharynx and mouth, as well as metastatic tumors which are accessible to either the implantation of emanation or the insertion of radium tubes, the dose is calculated so that the sum total of radiation approximates 130 per cent of the skin dose, 3 to 5 cm from the tubes or seeds implanted. This treatment is given during a period of one week to twelve days. Other developments with high voltage X-rays in cases with extensive neoplastic involvement have been calculated so that we can deliver more radiation to the tumor over a longer period of time in the hope of destroying cells which are in various stages of karyokinesis and at the same time giving the organism or the body a fair chance to recuperate from the assault of the large amount of radiation absorbed. This idea was promulgated in our minds by a careful study of the literature as to the effects of X-rays in the production of erythema as observed by Miescher and ourselves, that an erythema dose given in one sitting would produce slight flushing of the skin within twelve hours, with subsidence and then recrudescence of the erythema about the twelfth or fourteenth day which would persist for a period of a week or more and gradually diminish with another exacerbation at the end of six weeks or two months.

Experiments are being carried on with the idea of finding out how much radiation can be given in a certain length of time, maintaining as near

of thousands of examinations, these have conclusively proved that minor abnormalities frequently exist without detection and that the remedy if promptly applied has a very sound economic value to the individual. Naturally the medical profession in the same unselfish spirit which has characterized its work from the beginning is willing to take on this added responsibility in the early correction of abnormalities.

There is much food for thought in the undertaking. The average physician needs only to make a thorough physical examination correlating his data on a blank accepted as standard, this to be carefully filed for future reference. As to conditions which require the advice of a specialist, it is to be assumed that a general practitioner would not be an expert in examining eyes but a simple test with a careful questioning of the patient would indicate if trouble existed and the patient is naturally referred to a specialist. A conscientious general physical examination can be done by every physician, including tests of blood and urine, blood pressure, etc. There is

no mystery in this. Assuming a patient to be well without examination just because the physician chanced to know the family and forbears of the individual, would be a palpable error.

It is assumed that those general practitioners wishing to take up this work will acquaint themselves with a proper method of procedure so that they will not omit questions or examinations which are essential to an accurate and complete examination.

The movement for better health has reached national proportions and the American Medical Association having been convinced that it is time that the country united as a whole in some organized way, has invited interested groups to meet in Chicago in November when the present methods will be better standardized.

The future of Periodic Health Examination is essentially dependent upon the interest of the medical profession, a cooperation on the part of the public, and an intermediary who shall take care of the publicity necessary to awaken a general interest in the need of it.

## TANGIBLE RESULTS FROM POST GRADUATE LECTURES

Physicians like to see tangible results from any activity which they promote or support, and especially do they like to see their patients pleased. The principal justification for an activity is the tangible results which it produces.

There is need that physicians should take intensive courses of study in medical centers, but only a minority of physicians can afford the time and expense to take them. The duty of the State Medical Society is to the great mass of average doctors who compose its membership. The State Society at present should seek to raise the standard of practice for the many as well as to set a high standard for a few.

The Committee on Public Health and Medical Education is reporting that as the result of reading the report of one of the lectures sponsored by the State Medical Society, the medical staff of a hospital in a distant part of the State appointed a committee to propose a standard method of managing the toxemias of pregnancy

in that hospital (see page 1038). This result is both tangible and practical, and is the kind that should follow the State Society lectures. On the other hand, the lectures should be such that frequent opportunities for practical results may follow—and this means that the lectures should be on topics which a doctor will be likely to put to frequent use.

A specialist in obstetrics would have found very little that was new in the lecture to which we refer. All its information had been set forth in medical literature with which specialists were familiar. The originality and peculiar value of the lecture consisted in the choice and presentation of facts which can be put to practical use at the bedside, and which the average doctor would not otherwise have learned. The teacher who brings a new fact to the attention of many doctors does a piece of work whose value ranks with that of the discovery of the fact.

## A NEW DEPARTMENT

With this issue of the JOURNAL we are introducing a Department called "Medical Progress," which will appear in each issue and will consist of abstracts of the more important articles appearing in the current medical journals of this country and of Europe. We are fortunate in having secured the assistance of Dr. Thomas L. Stedman, formerly Editor of the *Medical Record*, who will have editorial charge of this Department.

In preparing the material for this section the aim will be to select for comment and review such articles as embody the latest advances in the various branches of medicine and surgery, or those which contain novel ideas and suggestions of actual value to the physician or surgeon in his daily practice. The new Department will thus be an essential part of the comprehensive plan for Graduate Education which has been instituted by the Medical Society of the State of New York.

# EDITORIALS

The Medical Society of the State of New York is not responsible for views or statements, outside of its own authoritative actions published in the JOURNAL. Views expressed in the various departments of the JOURNAL represent the views of the writer

For list of District Branch Officers, Standing Committees and Special Committees, see October 15 JOURNAL, advertising page third cover

## PERIODIC HEALTH EXAMINATION

A public interest has been aroused in the matter of Periodic Health Examination which bids fair to claim a local, State and national interest. There has been so much said about it and so much propaganda has been forthcoming that it has gathered unto itself a certain air of mysticism. There is nothing mysterious about it. Public agencies of every character have long striven to conserve public health.

The idea that a healthy community is a great economic asset to the State is well founded. Our City and State Boards of Health have slowly but surely improved the health of the community. Their work which started in a determination to reduce the death rate has grown into the broader field of disease prevention.

A most remarkable piece of constructive work was accomplished when public laboratories were

established and an ample supply of anti-diphtheritic serum, tetanus serum, anti-rabic serum and various other preventative and curative serums were offered through these public sources.

The State has likewise demonstrated a commendable interest in the health and welfare of the rural districts. Public Health Centers have been established and demonstrations given to impress upon the people the fact that their health and well-being was a vital requirement for good citizenship.

We now reach another advance and this comes as a challenge and responsibility to the licensed physicians of the State. The idea that a Periodic Health Examination would disclose enough data to prevent the development and advance of definite diseases has been well established. Outside statistical agencies have collected the results

## MEDICAL PROGRESS

**Sympathectomy in Angina Pectoris**—About four years ago Jonnesco reported in *La Presse Medicale* a case of angina pectoris occurring in a man of 38 years, in which he resected the left cervical sympathetic nerve with the superior middle and inferior cervical and the first thoracic ganglia. The result was an apparent cure, the patient reporting, four years after the operation, entire freedom from his previously agonizing pain. The object of the operation was to suppress the pain by interrupting the transmission of impulses from the cardio-aortic plexuses, though of course the condition previously exciting the attack was not thereby removed. This first success encouraged a repetition of the operation by Jonnesco, Tuffier, and others, until at the present time the number of reported cases is such as to establish the justifiability of the measure for the relief of true angina pectoris in properly selected cases.

This aspect is discussed by Samuel A. Levine and Francis C. Newton in the initial number of the *American Heart Journal*, October, 1925, 1, 1. They confirm reports submitted by others showing that cervical sympathectomy affords striking relief in certain cases, and stress the point that the proper selection of cases ought to diminish markedly the immediate surgical mortality, and also give to those operated upon a reasonable expectation that they may live for an appreciable length of time to enjoy their improved health. The writers emphasize the absolute necessity of an accurate diagnosis before operation is undertaken, and especially insist that cardiac infarction be not confounded with angina pectoris. Furthermore the study of each patient should indicate that there has not been any congestive heart failure, that the musculature of the heart is satisfactory, and preferably that there is no valvular disease. The authors give a detailed report concerning seven patients who were selected for sympathectomy. They were all alive three months to two years after operation. Three were rendered absolutely free from anginal attacks and have remained so, three continued to have typical anginal attacks but were nevertheless considerably improved, in that it required a greater effort to bring on the attacks. In one case there was no change whatever. It is urged that cases be reported in detail so that it will be possible to form a judgment as to the type of patient to be operated upon.

A warning against the inclusion of the stellate ganglion in this resection of the sympathetic has,

however, recently been uttered by Danielopolu and Marcu (Paris correspondence of the *Lancet*, October 24, 1925, cci, 5330). In the authors' experiments the myocardium was first weakened by occlusion of the coronary arteries and then the superior thoracic ganglion was excised. The modification resulting therefrom in the electrocardiogram was regarded by them as of very serious clinical import, indicating a blocking of the cardiac motor fibres. The operation proposed by Danielopolu and Marcu in place of the Jonnesco procedure consists in excision of the cervical sympathetic, sparing the superior cervical and first thoracic ganglia, resection of the vagus and all its branches which supply the thorax, and resection of the rami communicantes uniting the inferior cervical and first thoracic ganglia to the lowest cervical and first dorsal nerves. The advantage of this operation is that, while a large number of cardio-aortic sensory fibres are resected, the important afferent fibres which pass through the stellate ganglion remain unimpaired.

**The Surgical Treatment of Mitral Stenosis**—H. S. Souttar (*British Medical Journal*, October 3, 1925, ii, 3379) reports a case in which he operated for mitral stenosis, and takes the occasion to illustrate the technique he has adopted. In a girl, aged 15, with a history of chorea and mitral stenosis, with many relapses and increasing failure of compensation, rest in bed made it appear that the heart was unable to reestablish compensation, and it was therefore decided to attempt to relieve the stenosis by surgical means. Under intratracheal anesthesia, a curved incision was made along the fourth intercostal space, up along the middle of the sternum, and onward along the first left intercostal space. On the outer side of this area, a short horizontal incision was made along each of the three ribs exposed, and through these incisions the ribs were divided. When the flap was turned outward an area of the chest wall about five inches square was exposed. The chest wall was divided a little within the line of the original incision by cutting through the muscles and costal cartilages, the flap so formed was turned outward, the pleura being included with it. After waiting five minutes for the rapid action of the heart to subside, the pericardium was opened by a vertical incision three inches long, in the center of which the left auricular appendage came prominently forward. Two sutures were passed through the upper and lower margins of the appendage, so that it could be readily drawn forward. As the heart was beating very

## PROBLEMS OF ORGANIZED MEDICINE

The Medical Society of the State of New York is often confronted with new problems for whose solution the public looks to physicians. Modern life requires a complex adaptation to new conditions which arise out of civilization itself. The means of rapid travel, for example, bring increased opportunities for the spread of infectious diseases, such as influenza, and the human race is still engaged in a constant struggle for existence.

While physicians are marvellously well trained to deal with individual cases of sickness, they as individuals can do little to combat the extensive causes of sickness which arise from communal origin. Doctors must have the assistance and support of the great mass of people before they can control such conditions as malaria and hookworm. These problems must be solved by organizations of physicians cooperating with society.

Social and philanthropic organizations have provided the means for studying public health and for spreading an extensive propaganda for the prevention of diseases and the promotion of vigor and long life. These organizations have individual physicians as advisors, but to the great mass of physicians they often seem visionary and impractical because the average physician acts on his own individual initiative and deals principally with sick persons as individuals. The physician of today has his hands full in dealing with individuals who come to him, each seeking relief from his own infirmity.

The individual physician is not able to solve community problems in medicine because he is only an individual and his voice does not reach beyond the limited circle of the comparatively few who employ him. But an organization of physicians can speak with an authority which is denied to the individual doctor.

Physicians generally are acutely aware of their opportunities to do public service, and to advance the cause of community health. There is a very real field for the practice of civic medicine by medical organizations as distinguished from individual physicians.

The field of the practice of civic medicine is largely preempted by lay organizations, and the reason is obvious. Civic medicine is concerned principally with social conditions, and the lay organizations are founded and managed by sociologists who have made special studies of economics, criminology, education, housing, and other conditions that have a deep effect on life and health. Physicians have said that the remedy of social conditions is extremely difficult because the people are ignorant and refuse their cooperation. The sociologists and lay organizations have taken the doctors at their word, and say "If the doctors fail in the practice of civic medicine because of the ignorance of the people, we will educate the people by the use of nurses, exhibits, lectures, and any other means of reaching them."

The obvious field of lay health workers is that of educating the people and getting them to avail themselves of medical advice both privately and collectively.

The obvious duty of physicians when the lay workers refer cases to them is to accept the cases, and give the best advice possible, and thank the workers who sent them.

The happy cooperative state of affairs has not entirely come to pass. Lay workers have sometimes told doctors what to do in a medical way, and doctors have sometimes said that the sociologists were often attempting the impossible. But order is rapidly evolving in the overlapping fields of medicine and sociology. Evolution has always consisted in developments along all possible lines of variation, some practical and some useless or harmful. All kinds of new devices are tried and only the good survive. We may be pessimistic as we view the numerous failures in social evolution, or we may be optimistic as we consider the successful results and the promising outlook for the future.

The most optimistic sign of all is that medical societies—county, state and national—are entering heartily into their own peculiar half of the field of the practice of civic and social medicine.

## PRESERVE YOUR JOURNALS

We appeal to our members to preserve their Journals. Our special reason for making this request is that the Journals contain descriptions of the activities of the State Medical Society and its officers and committees.

As the officers go about the State we are often asked about the policies of the State Medical Society, and about what has been done, and in nearly every instance they have been able to point to the answer in some recent number of the Journal.

We realize that no one can grasp all phases of State Medical Society work by a casual

reading of everything in the Journal, but every doctor has occasion to look up some phase of work which is fully described in the Journal and nowhere else.

It is a very great convenience to both the officers of the State Society and to an inquiring member to be able to turn to the Journal pages describing a certain activity in which the member is interested. Members who preserve their Journals will find them exceedingly interesting and useful after six months or a year have elapsed.

*ton Medical and Surgical Journal*, October 22, 1925, cxciii, 17) endeavors to show that the prevalent belief in the inefficacy of specific treatment of cardiovascular syphilis, when present to the degree that symptoms or demonstrable signs exist, is fallacious. It has been conclusively proved that antiluetic treatment has resulted in the amelioration of symptoms, especially the harassing pain of angina pectoris of luetic origin, and has been shown to be of benefit in all cardiac deficiencies which have a specific basis. A review of the statistics of autopsy services in large hospitals shows that cardiovascular syphilis occupies a prominent position, and a large number of these cases reflect directly the inefficacy of the former nonspecific methods of treatment. In early cases, the administration of arsphenamine (or of one of the allied arsenicals) is the treatment par excellence. It is but rarely, however, that cardiovascular syphilis is susceptible to diagnosis early enough for one to be as secure in approaching the treatment as one is in the case of chancre or of the secondary manifestations. It has been shown that there is a fairly large percentage of cases where, in spite of clear-cut evidence of the presence of aortitis, aortic regurgitation, or aneurysm, the Wassermann is repeatedly negative. In the clinic of the Boston University School of Medicine, therefore, less attention is laid to the Wassermann and more to the other factors in diagnosis. The author's plan is to begin with a short course of six mercury or bismuth injections given intramuscularly. Weekly injections of arsphenamine are then begun, the initial dose being 0.15 Gm. If this is well tolerated the dose may be increased to 0.4 Gm. About four to six injections should constitute a course. Concomitantly the patient is given potassium iodide in increasing doses reaching 100 grams or more daily. Whenever it is possible arsphenamine or one of the allied arsenicals, should be given, as this treatment is far more effective than any other form of therapy.

**Oxygen in the Treatment of High Blood Pressure** — According to Simon (*Klinische Wochenschrift*, October 1, 1925, iv, 40), this subject is not entirely new, but it is only recently that inhalations have been applied systematically for the purpose stated. It is hardly the long looked for hypotonic remedy, but should certainly prove a valuable accessory to other measures. Loewy was the first to show that the normal pressure is but little influenced while pathologically high pressures of all types can be brought down—the higher the original systolic pressure the greater the reduction, the diastolic being little influenced. The author has followed up the work of Loewy, and was able to corroborate his claims. He then tested the inhalations on a series of se-

vere cases of chronic disease with high pressures. The patients were made to inhale six liters of O during 1 to 1½ minutes, either once or twice daily, for an interval of five days, ten days, etc., according to the case. In an elderly patient with arteriosclerosis and cardiac decompensation the blood pressure had varied from 165 to 200. After eight days of inhalations the pressure had fallen to 135, but when the inhalations were intermitted it returned to its former height. After a second course it was brought even lower—110 to 120. The author relates other similar cases with the same results. The patients took no other medication and no other treatment of any kind is mentioned.

**Collapse of the Lung** — Edward D. Churchill (*Archives of Surgery*, October, 1925, ii, 4) believes that the so-called massive collapse of the lung, which has been receiving increasing attention as a postoperative pulmonary complication, is but a special type of pulmonary atelectasis, and that, at least in the majority of instances, it occurs as a result of the same etiological factors. The most important diagnostic sign of postoperative massive atelectasis is displacement of the heart and mediastinum toward the affected side. The auscultatory signs, which vary with the extent and nature of the pathological process, are correlated with the Roentgen ray picture. Experimental and clinical observations indicate that atelectasis results from the combined action of weakened respiratory force and bronchial obstruction. These two factors may be caused by different agencies, and play rôles of varying importance in different cases. Pulmonary embolus does not cause atelectasis except as an accompaniment of the subsequent fibrosis, though it is possible that an area of pulmonary collapse may alter the pathological course of an embolus which chances to lodge within its borders. A review of the literature gives no direct evidence for the belief that atelectasis in itself favors the development of pneumonitis.

**"Petty Signs" of Tuberculosis** — Nigoul-Foussal gives an account of certain forerunners of acute outbreaks of tuberculosis of the lungs and meninges which are apparently partly supplied by the anatomo-physiological predisposition to disease and otherwise are the result of minimal infection with tubercle bacilli. He justifies his use of the expression, "petty signs" (by which is implied prodromic rather than insignificant), because this is also in use in French writings on Bright's disease, arteriosclerosis and hepatic insufficiency. The author's petty morbidity of tuberculosis differs from that often given, doubtless because he refers essentially to certain clinical and pathological types, and not to tuberculosis as a whole.

rapidly, the wound was covered with hot saline pads and a subcutaneous injection of 1/100 grain strophanthin was given. After ten minutes the heart steadied down to 120, and the blood pressure, which had fallen to 60 mm, returned to 90 mm. The auricular appendage was drawn forward, a soft curved clamp was applied to its base, and it was incised in an anteroposterior direction with scissors. Into this opening the left forefinger was inserted, the clamp was withdrawn, and the appendage was drawn over the finger by means of the sutures. The whole of the interior of the left auricle could now be explored with ease. The finger was passed into the ventricle through the orifice of the mitral valve without encountering resistance, and the cusps of the valve could be easily felt and their condition estimated. As the stenosis was of moderate degree and was accompanied by little thickening of the valves, it was decided to limit intervention to such dilatation as could be effected by the finger. After breaking down adhesions the finger was withdrawn, but at the critical moment of withdrawal the lower retaining suture cut through, and the appendage slipped back into the pericardium, there was a sudden gush of blood which was, however, instantly checked by pressing the appendage against the heart. The opening was now held securely closed with the thumb and finger, while an assistant passed a silk ligature around the appendage and tied it off. The chest was closed, after removing the blood that had escaped into the pleural cavity, and on the conclusion of the operation the general condition of the patient was indistinguishable from that at the beginning. At the end of three months the patient declared that she felt perfectly well, although she still became somewhat breathless on exertion. The author expresses himself as impressed by the mechanical nature of these lesions and the practicability of their surgical relief.

**Ischaemia Cordis Intermittens**—L. Bischoff (*Lancet*, October 10, 1925, cxi, 5328), using the above terminology, describes a group of anginoid phenomena, affecting patients between the ages of 30 and 70 years, mostly males, after more or less brisk walking or climbing, or any hard exercise. There is a disagreeable pain behind the sternum, which passes into a feeling of spasmodic contraction with oppressive sensations of anxiety, culminating in such a sense of approaching dissolution that the patients are obliged to stop. It may lead to complete loss of consciousness. Dyspnea is absent. Often, after a rest of a few minutes, the patient is able to continue his walk in perfect comfort, but soon after the resumption of exercise pain returns. The history of all patients reveals the same phenomena. The author draws a distinction be-

tween this affection and true angina pectoris, noting that the former is excited by exercise, while the latter usually occurs at night or during rest. The complex of symptoms under consideration is connected with an insufficient blood supply to the heart muscle. In these cases, as in ordinary angina, the prognosis will depend on the etiology of the ischemia, i.e., on the occurrence of alterations in the vessels, on the extent of such alterations, and on the state of the aorta, of the heart muscle, and of its reserve power. The author has never heard a double first sound (during quiet breathing in the entire phase) in cases of ischaemia cordis intermittens, while it has been repeatedly observed to be present in true angina pectoris. One patient was observed fluoroscopically during an attack. No alteration worth mentioning (dilatation for example) was noticed, but the apparent pulsations and the visible range of contractions were small.

**The Use of Urea as a Diuretic in Advanced Heart Failure**—J. Hamilton Crawford and J. F. McIntosh (*Archives of Internal Medicine*, October, 1925, xxxvi, 4) administered urea in doses of 30 to 60 Gm. a day to eight patients with advanced heart failure, and then estimated the urea in the blood and urine by the method of Van Slyke and Cullen, the chloride in the urine by a Volhard titration, and the chloride in the plasma by the method of Van Slyke. The result of the administration of the urea was a marked increase in urine volume. The drug was particularly useful in cases in which an adequate water excretion was not maintained after the edema fluid had been removed by other measures. In some cases it relieved the edema when other remedies had failed. The increase in urine output followed closely the curve of urea excretion. With continuous administration the daily urine volume was maintained at an almost constant level. The response after administration was rapid, but the effect passed off in a short time unless the dose was repeated. The changes in the urine volume and in urea excretion were found to be dependent upon the concentration of the urea in the blood. In several cases in which there was a subnormal index of urea excretion which seemed ascribable to advanced heart failure, the index tended to improve with urea administration, along with a general improvement in the clinical condition. No toxic symptoms of any significance were observed. The authors suggest that urea is a useful diuretic in cases of cardiac failure with edema in which treatment of the heart condition has failed to remove the edema or maintain an adequate water excretion.

**The Value of Specific Treatment in Cardiovascular Syphilis**—Bernard I. Goldberg (*Bos-*

# LEGAL

By GEORGE W. WHITESIDE, Esq.  
Counsel, Medical Society of the State of New York

## THE GOVERNMENT OF A PROFESSION

The regents was created in 1784, the Constitution of the State, Article 9, Section 2, continues their existence subject to their powers being modified or changed by the legislature. In Section 51 of the Education Law we find

*"Conformable to law, the regents may supervise the entrance regulations to, and the licensing under, and the practicing of, the profession of medicine"*

We have long been familiar with the action of the regents in supervising "the entrance regulations to, and the licensing under" of the profession of medicine, but little seems to be known of the exercise of their power, under existing laws, of the supervision of the *practice* of the profession of medicine.

The board of regents consists of three more than the existing judicial districts of the State, which means that their membership consists of twelve. They hold office in the order of their election, so that the term of one regent expires each year and his successor is elected by the legislature on the joint ballot of the two houses, which appears to give a regent a twelve-year term.

Under the present law the regents may revoke the license of a practitioner of medicine, or annul his registration, or do both, for certain statutory violations of professional conduct. The charges are heard in the first instance by three members of the board of medical examiners. This committee makes a written report of its findings and recommendations to the board of regents. Upon the examiners' report the regents may, in their discretion, revoke a license or annul a registration, so that the trial tribunal consists of three medical examiners, whose only power is to hear evidence and make a report. The ultimate decision of the action to be taken rests in the discretion of the regents.

The board of medical examiners consists of nine members appointed by the regents, who hold office for three years. They must be physicians of at least five years' practice. They receive an annual compensation of not less than four thousand dollars, payable from the fees received under the article respecting the practice of medicine. The chief duty of the board of medical examiners consists in submitting to the regents a list of suitable questions for examination of candidates for license—the regents prepare the question papers. The medical examiners examine the papers and mark the answers and transmit their

report to the regents. This is the practice provided for by statute in the present medical practice act enacted eighteen years ago.

In the legal profession there is a similar examining committee, whose entire functions are devoted to the preparation of questions and the marking of papers of applicants for admission to the bar. The bar examiners exercise no quasi-judicial functions in the regulation of the profession or in acting as a trial committee or court for members of the profession who may be placed under charges.

The preparation of questions to be submitted to the young men applying for admission to practice medicine requires one type of ability, the exercise of judicial functions for the control of the profession at large—whose members have already been admitted to practice, many of them for many years—calls for a different and more varied kind of experience and understanding. Keep in mind, please, that as has already been quoted from the law, the regents supervise the *practice of the profession of medicine*. Under that power, at the present time, *every member of the medical profession* is subject to the *supervision* of an essentially lay body. The statute under which the regents were first granted the power to revoke licenses for causes other than conviction of felony or irregularity or fraud in procuring a license was the medical practice act of 1907, and in 1910 Section 51 of the Education Law gave the regents power of supervision over the practice of medicine.

The regents, under the present act may, after trial by them, revoke a physician's license who is guilty of "(a) fraud or deceit in his practice," (b) guilty of a crime or misdemeanor, (c) guilty of being an habitual drunkard or drug addict, (d) guilty of undertaking to perform an abortion, and (e) guilty of offering or undertaking to give contraception information or advice. Thus, disciplinary power over the medical profession resides now without the ranks of the profession and in a lay body—a body whose chief function is the control of education from the common school through the university, a body whose educational duties give it little time or background for the study and understanding of the complex problems surrounding professional misconduct in the medical profession. In the choice of these regents who are lay judges of the medical profession, the profession has no voice. In the selection of the medi-

He attempts to rationalize these evidences. Thus, one group of symptoms may be referred wholly to habitual low blood pressure—chilliness, subnormal temperature, lassitude. In another group the alimentary canal furnishes the symptoms and the author attributes them to a basic mucomembranous enteritis which is responsible for constipation, nausea, vomiting, capricious appetite, etc. A third characteristic is overreaction to protein injections of all kinds which may be further associated with oversensitiveness to the action of certain drugs, as quinine and aspirin. A symptom not usually mentioned under forerunners of bacillary tuberculosis is early obesity. This may be due to some endocrine anomaly, but the author suggests that it may be of toxigenic nature, and cites cases in which slight toxemia has led to obesity. Individuals with this symptomatology may remain for years in apparent health, only to succumb suddenly to one of the acute forms of tuberculosis. *Le Bulletin Médical*, Sept 2/5, 1925, xxxiv, 36.

**Splenic Opothrapy in Tuberculosis**—Bayle of Cannes has used this treatment for his tuberculous patients since 1903 (*La Presse Médicale*, September 23, 1925, xxxiii, 76). Justification for its use was furnished by the results obtained in induced laboratory tuberculosis of animals, the rationale being in part a remarkable and rapid action on the blood, comprising increase of both red and white cells (lymphocytes) and hemoglobin. The waste of phosphates was also checked while the blood calcium content was increased. The bacilli were found to be diminished in numbers, and the formation of fibrous tissue and cicatrization was promoted. Many laboratory men are quoted in support of these claims, which apparently may be verified by anyone. The author notes precisely the same consequences in his human subjects and mentions that a single hypodermic injection of the extract will cause an increase of the red cells from 4 to 5 millions. Weight and general condition gain, the lesions are shown by objective tests to heal, and the bacilli disappear from the sputa.

The remedy may be given by the mouth in the incipient or threatened case, and as an adjunct to the hypodermic method, the latter is, however, required in all active cases. One or two ampoules of 5 cc each are injected at such intervals that a dozen injections shall have been received at the expiration of 22 days. The author appears to employ no other medication, although he goes intensively into a consideration of the diet. In addition to his own observation, his colleagues in Cannes and nearby, both in private and sanatorium practice, have reported favorable results. The patients in the second and third stages taken jointly show a recoverability of 75 per cent.

Similar results were obtained by Tremolieres and Colombier by irradiation of the spleen (*Archives d'Electricité med.*, xxxi, 79). They used a weak dose (about 1H) once a week for fifteen weeks. The results noted were marked improvement in the general health, increase in weight, cessation of the night sweats and cough, and reduction in the daily fluctuations of temperature.

**Prevention of Senescence by the Brown-Sequard Testicular Extract.**—Zoth contributes to the *Wiener klinische Wochenschrift* of September 24, 1925, xxxviii, 39, an account of his personal experience with this substance. He began to test the extract with Pregl in 1896 when he was thirty years old. A preliminary report was made at the time and the author has continued his use of the extract for the intervening thirty years in the aim of slowing up the involutory tendencies of man. Although he has used the remedy on others, most of the paper deals with his own case and with the technique of administration which he has continually sought to perfect. He prepares the extract from the glands of sexually mature bullocks, and still follows the old Brown-Sequard-d'Arsonval technique of preparation. He learned that one short course of treatment every summer is sufficient and that attempts to push it are dangerous in that they cause symptoms of serious cardiac mischief. He is sure that the results obtainable with the proper technique surpass any of the new contemporary procedures, including the direct gland implantation and Steinach ligation. The course of treatment should last from two to four weeks. The total amount of glycerin extract, which is injected beneath the skin of the abdomen, should be 20 to 30 cc, and the single dose, 1 to 1.5 cc diluted with twice the quantity of distilled water. In regard to results the author is satisfied with his life-long personal experiment, although he realizes the difficulty of convincing the public with the experience of one individual. As an out-door athlete and gymnasium devotee he finds his capacity for physical exertion is maintained, and he believes he has a superior resistance to disease. Despite the harrowing experience of the war and after-war years he shows no signs of senescence in his 61st year.

In this connection it is interesting to recall the observation of K. M. Walker in the *Lancet* of January 5, 1924, who holds that the internal secretion of the testis is formed by the tubular cells, the interstitial cells being merely trophic in their function. They simply store up nutritive material for use by the tubular cells in case of emergency, and the mere fact that the interstitial cells increase in number after ligation of the vas deferens is no proof that the output of internal secretion has been increased.

## GRADUATE EDUCATION

The work of the Committee on Public Health and Medical Education is growing beyond expectation. While it had been expected that considerable stimulation would be required in order to create a demand for courses of study, experience has shown that the doctors throughout the State are ready and eager to attend the courses. The field is ready, and the demand for instruction is already existing. The Committee has, therefore, been relieved of the preliminary work of arousing an interest in its activities.

The Committee found that several forms of graduate medical instruction were already being conducted throughout the State. There was first the post-graduate instruction given by the medical schools and a few hospitals in the larger centers. These courses were mostly intensive and required attendance at the teaching center and much collateral study and investigation. These courses are for the training of leaders and specialists, and they need little stimulation or aid from the Committee.

A second form of instruction was that given to health officers, under the auspices of the State Department of Health. At least twenty-five of these courses have been given. They are designed not merely to teach health officers how to perform their newer round of required duties, but they gave the health officers a broad view of the whole field of public health and preventive medicine, and showed the student how he could practice these newer branches of medicine in his everyday, unofficial work. Over 500 doctors had taken extensive department of health courses, and their commendation of the courses was practically unanimous.

A third form of graduate medical instruction was that of courses in special subjects made available to physicians in their own home towns, while the students continued to follow their daily medical rounds. These courses were developed under such varying conditions as Kings County—the largest Borough of Greater New York—and Suffolk, Jefferson, St. Lawrence, and Orange counties, all of which are very largely rural.

The Committee deemed it wise to combine the plans of the State Department of Health with that of local teaching centers, and to offer courses for which the State Department of Health was already prepared, especially those in pediatrics and obstetrics.

The intimate co-operation of the Department of Health with the Medical Society of the State of New York has been most fortunate, and calls for the combined courses are coming to the Committee faster than the facilities for giving them

can be organized. But the Committee wishes it understood that the co-operative courses are by no means the only ones that are being planned, it expects to be able to offer equally good courses in diseases of the heart, kidneys, nervous system and other parts of the body.

The Committee has its headquarters in the Building of the Medical Society of the County of Kings, Brooklyn, at 1313 Bedford Avenue, near Atlantic Avenue. There files are being accumulated containing information regarding every county in the State. This information has been derived from every possible source—correspondence, the Medical Surveys published in the *JOURNAL*, personal interviews, questionnaires, the State Department of Health, and any other available source, and the information is constantly growing in extent and value.

A word as to the questionnaire, a copy of which was printed on page 941 of the October first issue of the *JOURNAL*. This questionnaire contains the subjects on which definite information is desired by the Committee, and which must be available in order that the Committee may allocate its resources intelligently.

We urge the officers of the county societies to send their answers promptly and fully.

New courses have recently been started in several counties, as follows:

The Suffolk County Medical Society is starting a pediatric course in Southampton.

Washington and Warren counties are establishing a pediatric course, to be given in Glens Falls.

The Societies of Genesee, Livingston and Wyoming are uniting in a pediatric course in Batavia.

Chemung County will repeat the lectures in obstetrics which were given in Jefferson and St. Lawrence counties (see this *JOURNAL*, August, 1925, page 876).

The counties of Nassau, Columbia and Sullivan are completing the details for courses.

Doubtless other counties—Montgomery, for example—will institute courses independently of the State Society. The State Committee hopes that when county societies act on their own initiative, and put on courses which they arrange for themselves, they will send the Committee details of the courses planned and keep it informed of their activities.

The Committee is working out a plan by which the medical schools will co-operate in giving instruction. The Administrative Board and Faculty of the Buffalo University Medical School have voted unanimously to co-operate with the Committee in assigning teachers to nearby county

cal examiners who now are the trial committee of the regents, the profession has no voice

The ethical standards of the medical profession have been erected by the profession and not imposed upon it from without by any lay body. The profession has not been empowered to enforce these standards upon those unwilling to accept

them. Public confidence in the profession, so essential to the profession's economic stability and so vital to its successful public health activities, must spring from a will by the profession to regulate and elevate its standards by its own initiative rather than from a coercive exercise of police power by a body from without.

### NEGLIGENT TREATMENT OF RASH ON FACE

On a December evening a physician, in answering his door bell, was requested by a boy to call upon the boy's father. This physician, in response to the request, visited the home of the patient, who stated that he was down and out and sick, and had no money with which to pay the physician for any service that he might render. The physician told the patient that money was not a necessary requirement for the rendition of treatment.

Upon examination he found that the man was suffering from a slight bronchitis and prescribed an expectorant. On the following day the physician again called upon the patient, found that the condition was improving and that the patient was up and about and able to go out.

About a week after this visit the patient called at the doctor's office, at which time his face was swollen and reddish and there was a slight rash upon the face. The patient had a fear that the rash was erysipelas, which the physician, however, advised him was not the case. The patient gave a history of a syphilitic infection some years before. The doctor told him that the rash upon the face would undoubtedly clear within a few days, and he would thereafter have a blood test made. The patient fearing that the condition was erysipelas the doctor advised the patient to consult a specialist, but upon being told by the patient that he could not afford the services of a specialist, he then advised him to visit one of the city hospitals, where he would receive free treatment.

After the visit to the hospital the patient again returned to the doctor and stated that he had been advised at the hospital that the rash was not erysipelas. Several days later the patient again returned to the doctor, at which time the rash had almost completely disappeared from his face and the swelling had subsided.

The doctor heard nothing further from this patient until more than two years thereafter, when he received a letter from an attorney claiming that he had negligently and carelessly treated the patient and demanding a settlement of the claim. Refusing to meet the demand for a settlement, an action was instituted against the physician in the Supreme Court. Before a complaint was served in this action a second action was instituted in the Municipal Court. In the action in the Municipal Court a motion was made to dismiss the same on the ground that the cause of action was barred by the Statute of Limitations, which motion was granted. An appeal was taken by the plaintiff to the appellate court, but the judgment in favor of the defendant was affirmed by that court. The plaintiff having failed to serve his complaint in the Supreme Court action, a motion was made to dismiss the same on the ground of failure of prosecution, which motion was granted.

This physician, as compensation for his gratuitous service to the patient, was compelled to defend two actions of alleged malpractice which, fortunately, were terminated in his favor.

# MEDICAL PRACTICE ACT

AS FINALLY ADOPTED BY SPECIAL COMMITTEE OCTOBER 22, 1925

## AN ACT

To amend the public health law, in relation to the practice of medicine.

*The People of the State of New York, represented in Senate and Assembly, do enact as follows*

Section 1 Section one hundred and sixty-one of chapter forty-nine of the laws of nineteen hundred and nine, entitled, "An act in relation to the public health, constituting chapter forty-five of the consolidated laws," is hereby amended to read as follows

§ 161 QUALIFICATIONS No person shall practice medicine, unless registered and legally authorized prior to September first, eighteen hundred and ninety-one or unless licensed by the regents and registered under article eight of chapter six hundred and sixty-one of the laws of eighteen hundred and ninety-three and acts amendatory thereto, or unless licensed by the regents and registered as required by this article, nor shall any person practice under this article who has ever been convicted of a felony *involving moral turpitude* by any court, or whose authority to practice is suspended or revoked, [by the regents on recommendation of the state board] The conviction of [a] *such* felony shall include the conviction of any offense which it committed within the State of New York would constitute a felony under the laws thereof If a person convicted of a felony is subsequently pardoned by the governor of the state where such conviction was had, or by the president of the United States, the regents may, in their discretion, on application of such person, and on the submission to them of satisfactory evidence, restore to such person the right to practice medicine in this state, unless such conviction has been for misconduct in his professional capacity

Section 2 Section one hundred and sixty-four of such chapter is hereby amended to read as follows

§ 164 EXPENSES The fees derived from the operation of this article, *except as otherwise provided in section one hundred and seventy-five, subdivision five*, shall be paid into the state treasury and the legislature shall annually appropriate therefrom for the education department an amount sufficient to pay all proper expenses incurred pursuant to this article

Section 3 Section one hundred and sixty-nine of such chapter is hereby amended to read as follows

§ 169 LICENSES On receiving from the state board an official report that an applicant has successfully passed the examinations and is recommended for license, the regents shall issue to him a license to practice according to the qualifications of the applicant Every license shall be issued by the university under seal and shall be signed by the president and secretary of

the board and by the officer of the university who approved the credential which admitted the candidate to examination, and shall state that the licensee has given satisfactory evidence of fitness as to age, character, preliminary and medical education and all other matters required by law, and that after full examination he has been found properly qualified to practice Applicants examined and licensed in accordance with the provisions of this act who, when admitted to the licensing examination, were citizens of a foreign country, and who had declared intention of becoming citizens of the United States, shall, upon passing the examination, be issued a license valid for six years from the date of such declaration of intention and upon failure of such licensee to furnish evidence of his having actually become a citizen his license shall become invalid and automatically become revoked and his registration shall be annulled Applicants examined and licensed by other state examining boards registered by the regents as maintaining standards not lower than those provided by this article and applicants who matriculated in a New York state medical school before June fifth, eighteen hundred and ninety, and who received the degree of doctor of medicine from a registered medical school before August first, eighteen hundred and ninety-five, may without further examination, on payment of twenty-five dollars to the regents and on submitting such evidence as they may require, receive from them an endorsement of their licenses or diploma conferring all rights and privileges of a regents' license issued after examination The commissioner of education may in his discretion on the approval of the board of regents indorse a license or diploma of a physician from another state, provided the applicant has met all the preliminary and professional qualifications required for earning a license on examination in this state, has been in reputable practice for a period of ten years, and has reached a position of conceded eminence and authority in his profession Any physician, who has actually engaged in the practice of medicine in this state prior to September first, eighteen hundred and ninety-one, and who failed to register, although eligible to do so at the time, or any physician whose registration is not legal because of some error, misunderstanding or unintentional omission, may on the unanimous recommendation of the state board of medical examiners that he has submitted satisfactory proof of having complied with all the requirements prescribed by law at the time of his failure to register, or his incomplete registration, receive from the regents under seal a certificate of the facts which may be registered [by any county clerk and shall make valid his registration] *in accordance with this act* Before any license is issued it shall be numbered

societies, and the New York Post-Graduate Medical School has offered the services of over forty of the teachers

There is a field for courses in other subjects besides those for which the physicians have asked in the questionnaire. Tuberculosis, for example, is by no means a "Popular" subject, and yet it is one yet it is one of the most practical of all the courses which have been suggested. One county society is conducting a course of instruction to classes of physicians who came to the county sanatorium (see this JOURNAL, August, 1925, page 879). This course is an original piece of work, and is a demonstration of what other counties could do.

The subject of psychiatry is also exceedingly important. Dr. Van Etten emphasized it in his presidential addresses before all the District Branches. He showed ever increasing need for more hospitals for the insane, and the failure of the extensive building program of the State to keep pace with the demands for more and more beds. The State has hitherto met the demand by taking care of the mentally sick *after* their disease has become fully developed and chronic. The physicians of the State hospitals have begun to seek a solution of the problem by conducting clinics for the treatment of both incipient and apparently recovered cases, so that the cases will not have to be treated in the hospitals for long months and years.

A still further step is required, that of enlisting the aid of family physicians in advising for the care of "peculiar" children and "nervous" adults before their disease reaches the unsocial stage when hospital treatment is necessary.

Dr. Mortimer Raynor, Superintendent of the Kings Park State Hospital, has outlined a brief course of lectures on psychiatry for general practitioners, and the Suffolk County Medical Society has voted to sponsor a course to be given in the hospital. This course will be observed by the Committee with interest, for it is an attempt to adapt an exceedingly broad subject to the practical limitations of the general practice of medicine.

The Committee believes one of its functions is to promote a knowledge of periodic health examinations. It will, therefore, send a copy of the Manual on Periodic Health Examinations of the American Medical Association to every member of the Medical Society of the State of New York.

It will be issued with a special cover bearing the imprint of the State Medical Society. The copies are supplied by the A. M. A. at cost. The mailing will be done from the office of the State Society by the same means by which the State Journals are addressed, and so every member should receive a copy.

The distribution of the Manual is of great importance to every member of the Society. The Manual is of permanent value, and the Committee is distributing it with the expectation that every member will preserve it for reference.

We have recently heard of a striking example of the value of fundamental teaching, such as that given in the pediatric and obstetrical courses. The Staff of a small hospital in a rural district was discussing a death which was caused by the pernicious vomiting of pregnancy. The old-time treatment of induced abortion was given, and little else was done. The question arose regarding the modern treatment of the toxemias of pregnancy. One physician who had read a typewritten report of the Jefferson County lectures, asked "What is the modern treatment of vomiting of pregnancy?" He went further and investigated the histories of the cases of vomiting of pregnancy in the hospital, and found that practically all had been treated by the method of induced labor.

The discussion was renewed at the next meeting of the Staff, and the physician who had treated the last case presented an outline of the pathology and treatment of vomiting in pregnant women as he had culled it from modern literature. The members of the Staff to whom appendicitis and tubal pregnancies and pancreatic abscesses were familiar, were uncertain about the vomiting of pregnancy, and they voted unanimously to appoint a committee which should outline a method of managing the cases of toxemias of pregnancy which should be considered standard by the hospital. Further, one of the lecturers in the Jefferson County course has been invited to lecture to the physicians on the subject.

This is an example of the inspiring results which may be expected to follow a practical course in obstetrics such as that which the Committee is promoting.

CHARLES A. GORDON,  
*Chairman, Committee on Public Health  
and Medical Education*

mously find that said charges, or any of them are sustained, and shall unanimously recommend that the license of the accused be revoked or his registration be annulled, the regents may thereupon in their discretion, revoke said license or annul said registration, or do both. If the regents shall annul such registration, they shall forthwith transmit to the clerk of the county or counties in which said accused is registered as a physician, a certificate under their seal certifying that such registration has been annulled, and said clerk shall, upon receipt of such certificate, file the same and forthwith mark said registration "annulled." Any person who shall practice medicine after his registration has been marked "annulled," shall be deemed to have practiced medicine without registration. Where the license of any person has been revoked, or his registration has been annulled as herein provided, the regents may, after the expiration of one year, entertain an application for a new license, in like manner as original applications for licenses are entertained, and upon such new application they may in their discretion, exempt the applicant from the necessity of undergoing any examination.]

1 Every physician now lawfully practicing or authorized to practice medicine in this state shall, on or before January first, nineteen hundred and twenty-seven, apply to the treasurer of the commission on discipline for a certificate of registration with the regents upon a form which shall be furnished by said treasurer and every physician who shall hereafter be licensed to practice medicine shall, before engaging in practice, make such application for registration and pay the fee hereinafter specified.

2 A physician registering hereunder shall write or cause to be written on said blank so furnished by said treasurer his full name, office and residence addresses, the date and number of his license and such other facts for the identification of the applicant as a licensed physician as the commission on discipline may deem necessary and shall sign and verify the same before an officer empowered to take acknowledgements of deeds and deliver the same by mail or in person to said treasurer for filing with the regents.

3 The regents, upon receipt of such application, shall issue and send to every duly licensed physician in this state who has made such application, and upon payment of the fee of five dollars to the treasurer of the said commission on discipline, a certificate of registration issued under the seal of the university.

Upon March first, nineteen hundred and twenty-seven, or within ten days thereafter in the year nineteen hundred and twenty-seven, the regents shall publish and cause to be mailed to each such physician so registered and to the county clerk of each county and to the secretary of each duly incorporated state medical society,

a verified list of the duly registered physicians in this state. The names of physicians which after January first, nineteen hundred and twenty-seven shall be added to, as well as those that are withdrawn from said list, shall be reported by the regents quarterly to the secretary of each duly incorporated state medical society of which county medical societies are components and to the county clerk of each county. The list or lists of physicians prepared by the regents shall be so arranged that the name of each physician shall be grouped according to the county of his residence and in each group said names shall be arranged alphabetically.

4 Any licensed physician who having failed or neglected to register by January first, nineteen hundred and twenty-seven, as required by the provisions of this section, shall be required to pay upon registration, in addition to the fee of five dollars, a further fee of one dollar for each thirty days or part thereof, that he is in default, and any licensed physician who engages in practice and wilfully refuses or omits to register hereunder, shall be subject to a civil penalty of one dollar for each day that such wilful refusal or omission shall continue, provided that if the same continues for more than thirty days, the penalty thereafter shall be five dollars per day so long as the said wilful refusal or omission shall continue, provided, however, that such penalties shall not apply to any physician, duly licensed by the State of New York who, by reason of absence and practice in another state, or after a period of retirement from the practice of medicine, resumes practice in this state, if such physician, before re-entering upon such practice shall comply with the provisions herein by applying for a certificate of registration. Said penalty shall be recoverable in an action maintained in the name of the People of the State of New York by the attorney-general.

5 The penalties provided in this section for failure, neglect or omission of a duly licensed physician to register under this article shall be the only penalties that may be imposed therefor, and the legality of his license shall not be affected thereby, and such penalties may, for good cause shown, in the discretion of the attorney-general, upon recommendation of the commission on discipline, be remitted or compromised.

6 Each licensed physician shall conspicuously display his proper registration certificate in his office at all times.

Section 5 Section one hundred and seventy-one of such chapter as amended by chapter fifty-three of the laws of nineteen hundred and fifteen is hereby repealed.

Section 6 Section one hundred and seventy-two of such chapter is hereby renumbered Section one hundred and seventy-one.

Section 7 Section one hundred and seventy-three of such chapter as amended by chapter two hundred and eighty-two of the laws of nineteen hundred and twenty-four is hereby renum-

and recorded in a book kept in the regents' office, and its number shall be noted in the license, and a photograph of the licensee filed with the records. The record shall be open to public inspection, and in all legal proceedings shall have the same weight as evidence that is given to a record of conveyance of land.

Section 4 Section one hundred and seventy of such chapter is hereby amended to read as follows:

§ 170 REGISTRATION [Registry, revocation of license, annulment of registry. Every license to practice medicine shall, before the licensee begins practice thereunder, be registered in a book kept in the clerk's office of the county where such practice is to be carried on, with name, residence, place and date of birth, and source, number and date of his license to practice. Before registering, such licensee shall file, to be kept in a bound volume in the county clerk's office, an affidavit of the above facts, and also that he is the person named in such license, and had, before receiving the same, complied with all the requirements as to attendance, terms and amount of study and examinations required by law and the rules of the university as preliminary to the conferment thereof, that no money was paid for such license, except the regular fees paid by all applicants therefor, that no fraud, misrepresentation or mistake in any material regard was employed by anyone or occurred in order that such license should be conferred. Every license, or if lost, a copy thereof legally certified so as to be admissible as evidence, or a duly attested transcript of the record of its conferment, shall, before registering, be exhibited to the county clerk, who, only in case it was issued or endorsed as a license under seal by the regents, shall endorse or stamp on it the date and his name preceded by the words, "registered as authority to practice medicine in the clerk's office of \_\_\_\_\_ county." The clerk

shall thereupon give to every physician so registered a transcript of the entries in the register with a certificate, under seal that he has filed the prescribed affidavit. The licensee shall pay to the county clerk a total fee of one dollar for registration, affidavit and certificate. The regents shall have power at any and all times to inquire into the identity of any person claiming to be a licensed or registered physician and after due service of notice in writing, require him to make reasonable proof, satisfactory to them, that he is the person licensed to practice medicine under the license by virtue of which he claims the privilege of this article. When the regents find that a person claiming to be a physician, licensed under this article, is not in fact the person to whom the license was issued, they shall reduce their findings to writing and file them in the office of the clerk of the county in which said person resides or practices medicine. Said certificate shall be prima facie evidence that the person mentioned therein is falsely impersonating a

practitioner or a former practitioner of a like or different name. The regents may revoke the license of a practitioner of medicine, or annul his registration, or do both, in any of the following cases:

(a) A practitioner of medicine who is guilty of any fraud or deceit in his practice, or who is guilty of a crime or misdemeanor, or who is guilty of any fraud or deceit by which he was admitted to practice, or

(b) Is an habitual drunkard or habitually addicted to the use of morphine, opium, cocaine, or other drugs having a similar effect, or

(c) Who undertakes or engages in any manner or by any ways or means whatsoever, to procure or perform any criminal abortion as the same is defined by section eighty of the penal law, or

(d) Who offers or undertakes by any manner or means to violate any of the provisions of section eleven hundred and forty-two of the penal law.

Proceedings for revocation of a license or the annulment of registration shall be begun by filing a written charge or charges against the accused. These charges may be preferred by any person or corporation, or the regents may on their own motion direct the executive officers of the board of regents to prefer said charges. Said charges shall be filed with the executive officer of the board of regents, and a copy thereof filed with the secretary of the board of medical examiners. The board of medical examiners, when charges are preferred, shall designate three of their number as a committee to hear and determine said charges. A time and place for the hearing of said charges shall be fixed by said committee as soon as convenient, and a copy of the charges, together with a notice of the time and place when they will be heard and determined, shall be served upon the accused or his counsel, at least ten days before the date actually fixed for said hearing. When personal service or service upon counsel cannot be effected, and such fact is certified on oath by any person duly authorized to make legal service, the regents shall cause to be published for at least seven times, for at least twenty days prior to the hearing, in two daily papers in the county in which the physician was last known to practice, a notice to the effect that at a definite time and place a hearing will be had for the purpose of hearing charges against the physician upon an application to revoke his license. At said hearing the accused shall have the right to cross-examine the witnesses against him and to produce witnesses in his defense, and to appear personally or by counsel. The said committee shall make a written report of its findings and recommendations, to be signed by all its members, and the same shall be forthwith transmitted to the executive officer of the board of regents. If the said committee shall unanim-

hygiene, chemistry, obstetrics, diagnosis and the theory and practice of osteopathy, with actual attendance of not less than twenty months, which facts shall be shown by his or her diploma and affidavit, shall upon application and payment of ten dollars be granted, without examination, a license to practice osteopathy, provided application for such license be made within six months after the thirteenth day of May, nineteen hundred and seven. A license to practice osteopathy shall not permit the holder thereof to administer drugs or perform surgery with the use of instruments. Licenses to practice osteopathy shall be registered in accordance with the provisions of this article, and the word osteopath shall be included in such registration, and such license shall entitle the holder thereof to the use of the degree D O, or doctor of osteopathy.

*Section 8 Section one hundred and seventy-four of such chapter is hereby renumbered section one hundred and seventy-three and amended to read as follows*

**§ 174 PENALTIES AND THEIR COLLECTION** Any person who, not being then lawfully authorized to practice medicine within this state and so registered according to law, shall practice medicine within this state without lawful registration or in violation of any provision of this article, and any person who shall buy, sell or fraudulently obtain any medical diploma, license, record or registration, or who shall aid or abet such buying, selling or fraudulently obtaining, or who shall practice medicine under cover of any medical diploma, license, record or registration illegally obtained, or signed, or issued unlawfully or under fraudulent representations or mistake of fact in a material regard, or, who, after conviction of a felony, shall attempt to practice medicine, or shall so practice, and any person who shall in connection with his name use any designation tending to imply or designate him as a practitioner of medicine within the meaning of this article without having registered in accordance therewith, or any person who shall practice medicine or advertise to practice medicine under a name other than his own, or any person not a registered physician who shall advertise to practice medicine, shall be guilty of a misdemeanor. Any person who shall practice medicine under a false or assumed name, or who shall falsely personate another practitioner or former practitioner of a like or different name, shall be guilty of a felony. When any prosecution under this article, or under sections eleven hundred and forty-two, eighty, eighty-one, eighty-two, seventeen hundred and forty-seven of the penal law, and any amendments thereto, is made on the complaint of any incorporated medical society of the state, or any county medical society entitled to representation in a state society, any fine collected shall be paid to the society making the complaint, and any excess of

the amount of fines so paid over the expense incurred by the said society in enforcing the medical laws of this state, shall be paid at the end of the year to the county treasurer.]

### § 173 PENALTIES

1 Any person who shall,

(a) Sell or fraudulently obtain or furnish any medical or osteopathic diploma, license, record or registration, or aid or abet in the same, or

(b) Practice medicine under cover of any diploma, license, record or registration illegally or fraudulently obtained or signed or issued unlawfully or under fraudulent representation or mistake of fact in a material regard, or

(c) Advertise to practice medicine under a name other than his own or under a false or assumed name, and

2 Any person who not being then lawfully licensed and authorized to practice medicine within this state shall

(a) Practice or advertise to practice medicine, or

(b) Use in connection with his name any designation tending to imply or designate him as a practitioner of medicine, or

(c) Use the title "doctor" or any abbreviation thereof in connection with his name or with any trade name in the conduct of any occupation or profession involving or pertaining to the public health, or treatment or cure of any human disease, pain, deformity, or physical condition, unless duly authorized by law to use the same, and

3 Any person who during the time his license to practice medicine shall be suspended or revoked, shall practice medicine, shall be guilty of a misdemeanor

Such misdemeanor shall be punishable by imprisonment for not more than one year or by a fine of not more than five hundred dollars or by both such fine and imprisonment for each separate violation, and for a second offense shall be punishable by such fine and imprisonment

4 All courts of special sessions within their respective territorial jurisdictions are hereby empowered to hear, try and determine such crimes without indictment and to impose in full the punishments of fines and imprisonments herein prescribed

Such misdemeanors shall be prosecuted by the attorney-general in the name of the people of the state, provided, however, that nothing in this section shall be interpreted to prevent or impede the prosecution of such proceedings by the district attorney or any county having a population of five hundred thousand or more, when such proceedings shall have been initiated by him

5 The display of a sign or an advertisement bearing a person's name as a practitioner of medicine in any manner or by implication or containing any other matter forbidden by law

*bered section one hundred and seventy-two and amended to read as follows*

§ 173 CONSTRUCTION OF THIS ARTICLE This article shall not be construed to affect commissioned medical officers serving in the United States army, navy or marine hospital service, while so commissioned, or any one while actually serving without salary or professional fees on the resident medical staff of any legally incorporated hospital, or anyone while actually serving as an interne in a state hospital or other state institution in which medical service is provided, or any legally registered dentist exclusively engaged in practicing dentistry, or any person or manufacturer who mechanically fits or sells lenses, artificial eyes, limbs or other apparatus or appliances, or is engaged in the mechanical examination of eyes, for the purpose of constructing or adjusting spectacles, eye glasses and lenses, or any lawfully qualified physician in other states or countries meeting legally registered physicians in this state in consultation, or any physician residing on a border of a neighboring state and duly licensed under the laws thereof to practice medicine therein, whose practice extends into this state, and who does not open an office or appoint a place to meet patients or receive calls within this state, or any physician duly registered in one county called to attend isolated cases in another county, but not residing or habitually practicing therein, or the furnishing of medical assistance in case of emergency, or the domestic administration of family remedies, or the practice of chiropody, or the practice of the religious tenets of any church. This article shall be construed to repeal all acts or parts of acts authorizing conferment of any degree in medicine *causa honoris* or *ad eundem* or otherwise than on students duly graduated after satisfactory completion of a preliminary medical course not less than that required by this article as a condition of license. It is further provided that any person who shall be actively engaged in the practice of osteopathy in the state of New York on the thirteenth day of May, nineteen hundred and seven, and who shall present to the board of regents satisfactory evidence that he is a graduate in good standing of a regularly conducted school or college of osteopathy within the United States which at the time of his or her graduation required a course of study of two years or longer, including the subjects of anatomy, physiology, pathology, hygiene, chemistry, obstetrics, diagnosis and the theory and practice of osteopathy, with actual attendance of not less than twenty months, which facts shall be shown by his or her diploma and affidavit, shall upon application and payment of ten dollars be granted, without examination, a license to practice osteopathy, provided application for such license be made within six months after the thirteenth day of May, nineteen hundred and seven. A license to practice osteopathy shall not permit the holder thereof to administer

drugs or perform surgery with the use of instruments. Licenses to practice osteopathy shall be registered in accordance with the provisions of this article, and the word osteopath be included in such registration, and such license shall entitle the holder thereof to the use of the degree D O, or doctor of osteopathy.]

#### § 172 CONSTRUCTION OF THIS ARTICLE

1 This article shall not be construed so as to prevent the following (1) The practice of medicine in this state in obedience with the requirements of the laws of the United States, of any commissioned medical officer serving in the United States army, navy or public health service while engaged in the performance of the actual duties prescribed for him under the United States statutes, or (2) the practice of medicine in a duly incorporated hospital operating pursuant to the state charities law, or in a state hospital or other state institution in which medical service is provided, of a duly appointed member of the resident medical staff or of an interne, or (3) the practice of medicine by any physician duly licensed to practice medicine in a bordering state, who resides on a border of such neighboring state, whose practice extends into this state and who does not open an office or appoint a place to meet patients or receive calls within this state, or (4) any lawfully qualified physician in other states or countries meeting legally registered physicians in this state in consultation, or (5) the furnishing of medical assistance in case of emergency, or (6) the domestic administration of family remedies, or (7) the practice of chiropody, dentistry or veterinary medicine, providing those practicing are legally authorized and licensed under the laws of this state so to do, or (8) the practice of the religious tenets of any church, or (9) the fitting or selling of lenses, artificial eyes, limbs or other apparatus or appliances by any person or manufacturer of the same or the engaging in the mechanical examination of eyes for the purpose of constructing or adjusting spectacles, eyeglasses and lenses

11 This article shall be construed to repeal all acts or parts of acts authorizing conferment of any degree in medicine *causa honoris* or *ad eundem* or otherwise than on students duly graduated after satisfactory completion of a preliminary medical course not less than that required by this article as a condition of license. It is further provided that any person who shall be actively engaged in the practice of osteopathy in the State of New York on the thirteenth day of May, nineteen hundred and seven, and who shall present to the board of regents satisfactory evidence that he is a graduate in good standing of a regularly conducted school or college of osteopathy within the United States which at the time of his or her graduation required a course of study of two years or longer, including the subjects of anatomy, physiology, pathology,

1 The term of office of each of said members of said commission shall be five years, except that upon the taking effect of this act two members shall be appointed whose terms shall expire December thirty-first, nineteen hundred and twenty-seven, two members whose terms shall expire December thirty-first nineteen hundred and twenty-eight; two members whose terms shall expire December thirty-first, nineteen hundred and twenty-nine, two members whose terms shall expire December thirty-first, nineteen hundred and thirty, and two members whose terms shall expire December thirty-first, nineteen hundred and thirty-one, and as such terms expire they shall be filled by the addition to said commission of two members whose terms shall be five years. In the case of vacancy at any time by resignation, death or otherwise in the membership of the commission, the said vacancy shall be filled for the unexpired term in the same manner as provided for the original selection of such member.

2 Any duly incorporated state medical or osteopathic society having five hundred or more members may nominate candidates for members of such commission, not to exceed three nominations for each member of such commission to which such society shall be entitled hereunder. When the candidates are so nominated the chief judge of the court of appeals shall appoint for the terms specified herein as he shall determine, said members of the said commission, so that said commission shall consist of five members who have been duly nominated by the medical society of the state of New York, one member by the New York State homeopathic society, one member by the New York State osteopathic society, and upon his own nomination shall appoint three members of conspicuous professional standing. Each member of the said commission shall be a duly licensed physician of this state.

3 Said commission shall serve without compensation and shall annually, within ten days after the first day of January of each year, organize by the election of a chairman, secretary and treasurer.

4 Said commission shall have jurisdiction to hear and determine all charges against duly licensed physicians of this state for violation of the provisions of section one hundred and seventy-four hereof, and shall, upon the finding of such practitioner guilty, have jurisdiction to revoke and annul his license, annul his registration, suspend him from practice, or reprimand or otherwise discipline him. Proceedings against any practitioner under this section shall be begun by filing a written charge or charges against the accused. These charges may be preferred by any person, corporation or public officer, and they shall be filed with the secretary of the commission on discipline. The chairman of the said commission, when charges are preferred, unless he dismisses them as unsubstantial, may

designate one or more of the members of said commission to hear and report upon said charges to the said commission, or upon his motion may order the hearing of said charges to be held before an official referee who shall have power to hear and report thereon to said commission. The time and place of the hearing of such charges shall be fixed by the secretary of the commission as soon as convenient and a copy of the charges, together with a notice of the time and place when they will be heard shall be served upon the accused or his counsel at least ten days before the date actually fixed for said hearing. Where personal service or service upon counsel after due diligence cannot be effected and such fact is certified on oath by any person duly authorized to make legal service, the secretary of the said commission on discipline shall cause to be published for four times at least thirty days prior to the hearing, a notice of the hearing in a newspaper published in the county in which the physician was last known to practice, and a copy of such notice shall also be mailed to the accused at his last known address. All such notices of hearing of charges shall contain a plain and concise statement of the material facts without unnecessary repetition, but not the evidence by which the charges are to be proved, with a notification that a stenographic record of such proceedings will be kept if he demand it, and that the accused will have opportunity to appear either personally or by counsel at the hearing, with the right to produce witnesses and evidence upon his own behalf, to cross-examine such witnesses, to examine such evidence as may be produced against him and to have subpoenas issued by the said commission. Said committee or official to whom said charges were preferred shall make a written report of its findings and recommendations and same shall be forthwith transmitted to the secretary of the commission on discipline with a fair resume of the evidence. Said commission may thereupon act upon said recommendations as it shall deem fit, or may take further testimony if the same seem desirable in the interest of justice. Thereupon the said commission shall order, by a majority vote (the vote of each member of said commission to be recorded as part of the order) such degree of discipline as in their judgment the facts justify, or the dismissal of the charges, and/or the exoneration of the accused.

5 Any licensed practitioner found guilty under the provisions of this section, or whose license is otherwise revoked or suspended or registration annulled, or who has been refused registration, or who is otherwise reprimanded or disciplined by the commission on discipline under this article, may have an order of certiorari for the purpose of reviewing such determination returnable before the appellate division of the judicial department where the accused resides, but

shall be presumptive evidence in any prosecution or hearing that the person whose name is so borne is responsible for the display of such sign or advertisement and of a holding out and of the practice of medicine by such person for each separate day such sign or advertisement is anywhere displayed by anyone, but such presumptions are rebuttable by the defense. It shall be necessary to prove in any prosecution or hearing under this article only a single act prohibited by law or a single holding out or an attempt, without proving a general course of conduct, in order to constitute a violation.

6 In any action for damages for personal injuries or death against a person not licensed hereunder for any act or acts constituting the practice of medicine as herem defined, when such act or acts were a competent producing proximate or contributing cause of such injuries or death, the fact that such person practiced medicine as herem defined without being duly licensed shall be deemed *prima facie* evidence of negligence.

7 All violations of this act, when reported to the attorney-general and duly substantiated by affidavits or other satisfactory evidence, shall be investigated and if the report is found to be true and the complaint substantiated, the attorney-general shall prosecute such violation. The attorney-general shall appoint such inspectors as are necessary, to be paid from the funds received hereunder, to investigate promptly and thoroughly such violations and to procure where possible legal evidence of the same for prosecution of the offenders.

In the prosecution of any criminal action for violation of this article by the attorney-general or his deputy, said attorney-general or his deputy shall exercise all the powers and perform all the duties with respect to such actions or proceedings which the district attorney would otherwise be authorized or required to exercise or perform, and in such actions or proceedings the district attorney shall only exercise such powers and perform such duties as are required of him by the attorney-general or the deputy attorney-general so attending.

Section 9 Article eight of such chapter is hereby amended by adding thereto a new section to be known as section one hundred and seventy-four to read as follows:

#### §174 REVOCATION OF CERTIFICATES, ANNULMENT OF REGISTRATIONS AND DISCIPLINE

1 Whenever any practitioner of medicine shall be convicted of a felony, involving moral turpitude there shall be presented to the regents a certified or exemplified copy of the judgment of the court and/or the order of the commission on discipline wherein such conviction of felony was adjudged, and thereupon the registration of the person so convicted shall be annulled and his license revoked. And it shall be the duty of the

clerk of the court wherein such conviction takes place to transmit a certificate of such conviction to the regents. Upon reversal of such judgment by a court having jurisdiction, the regents, upon receipt of a certified copy of such judgment or order of reversal, shall vacate their order of revocation or annulment.

2 The license of a practitioner of medicine may be revoked, suspended or annulled or such practitioner reprimanded or disciplined in accordance with the provisions and procedure of this act in any of the following cases:

Upon finding after due hearing:

(a) That the physician is guilty of fraud or deceit in the practice of medicine or in his admission to the practice of medicine,

(b) That a physician has been convicted in a court of competent jurisdiction, either within or without this state, of a crime involving moral turpitude, or

(c) That a physician is an habitual drunkard, or addicted to the use of morphine, cocaine or other drugs having a similar effect, or has become insane, or

(d) That a physician is guilty of untrue, fraudulent, misleading or deceptive advertising, or advertising that he can cure diseases which are recognized by the medical profession as incurable, or advertising that he can cure or treat disease by a secret method, procedure, treatment or medicine, or that he can treat, operate and prescribe for any human condition by a method, means or procedure which he refuses to divulge upon demand to the commission on discipline, or

(e) That a physician did undertake or engage in any manner or by any ways or means whatsoever to procure or to perform any criminal abortion and/or to violate section eleven hundred and forty-two of the penal law.

(f) That a physician is guilty of the commission of any act which unfavorably affects the character, dignity, or interests of the medical profession and/or degrades its standard of honor or materially violates those principles of professional conduct that are ordinarily recognized by physicians and surgeons of the state as consistent with honorable practice among the average members of the medical profession in good standing.

Section 10 Article eight of such chapter is hereby amended by adding thereto a new section to be known as section one hundred and seventy-five:

§175 PROCEDURE IN DISCIPLINARY PROCEEDINGS Within sixty days after this act shall take effect there shall be appointed in accordance with the provisions hereof a commission which shall be known as the commission on discipline, which shall consist of ten members who shall be appointed by the chief judge of the court of appeals of this state in accordance with the provisions hereof.

## MEETING OF THE COUNCIL

A special meeting of the Council of the Medical Society of the State of New York was held at the rooms of the State Society, 17 West 43rd Street, New York City, on Thursday evening, October 29th, 1925

Dr Nathan B Van Etten, President, in the Chair

A quorum being present the meeting was called to order at 8 50 P M, and on roll call the following answered to their names

Drs Nathan B Van Etten, William H Ross, Frederick H Flaherty, E Eliot Harris, George M Fisher, Daniel S Dougherty, Charles Gordon Heyd, Owen E Jones, Edward R Cunneiffe, Henry L K Shaw, Charles A. Gordon, Andrew MacFarlane, William Warren Britt, John A Card, Joseph S Thomas, Horace M Hicks, Harry R Trick

Dr J E Jennings, Chairman Special Committee to Draft a Medical Practice Act, Mr George W Whiteside, Counsel, and Dr Joseph S Lawrence, Executive Officer, were also present

The following recommendations were on motion duly made and seconded, adopted

That a bill be prepared by Mr Whiteside and introduced into the Legislature to license nurses' registries, and promulgate rules and regulations by which a nurse when sent out on a case will carry with her a card containing information as to her qualifications, status, salary, etc

That the Council authorize the President to appoint a committee of three to discuss and study industrial problems of the State and confer with the State Industrial Commission

The President appointed Dr W Warren Britt of Tonawanda, Chairman, Dr Horace M Hicks of Amsterdam, and Dr Ransom S Hooker of New York City

That the request of the Chairman of the Committee on Scientific Work, for a special appropriation for a demonstration on Syphilis, to be held on Thursday of the Annual Meeting, be referred to the Executive Committee

That Drs John E Jennings, William P Healy, Edward W Weber, L Howard Moss, Samuel J Kopetzky, Isidore H Goldberger, Edward C Podvin and Henry Roth be elected members of the Committee on Arrangements

### PRACTICE OF MEDICINE ACT

Dr Jennings, Chairman of the Special Committee appointed to Draft a Medical Practice Act, presented the following report

Your committee appointed by the President, to

prepare a Medical Practice Act, reports as follows

The Committee consisting of Drs Jennings (chairman), Chalmers, Stanwix, Leitner, Fisher, Sadler and Winslow was appointed, and a meeting was held at the Academy of Medicine on June 25th, 1925, at which the President, Dr Van Etten Drs Jennings, Fisher, Chalmers, Stanwix and Sadler were present Plans were discussed, a general program adopted and the meeting adjourned

Seven subsequent meetings were held at the Columbia University Club on the following dates July 9th, July 23d, August 6th, August 27th, September 1st, September 22nd and October 22nd At all of these meetings, with the exception of the first preliminary meeting, legal counsel was present, Mr Oliver of Mr Whiteside's office for the second, third, fourth and seventh meetings, Mr Whiteside for the fifth, sixth and eighth meetings

Dr Winslow failing to report, Dr Flaherty was appointed in his stead and took his seat at the meeting on August 27th

Your Committee began its work by a consideration of the present Medical Practice Act and its bearing upon the conditions it is evidently intended to control

It may be said that public menace from those "holding themselves out as being able to diagnose, treat operate or prescribe for any human disease, pain, injury, deformity or physical condition" in the words of the law, arises from two sources

The first—those who operate without a license, who have not qualified according to law, the illegal practitioners

The second—those who having complied with the requirements of the law for admission to practice, abuse the confidence of the public, the profession and of the State

It is believed that the second group is responsible for as much or more actual evil as the first

The illegal practitioner of medicine should be detected and brought to justice like any other offender, by the department of justice

It seems no part of the proper duty of the Department of Education or of medical societies to enforce the law Hence the proposed act to amend the Medical Practice Act relieves the Department of Education of this burden by providing for one enrollment of all licensed physicians to

no such determination of the commission on discipline shall be stayed or enjoined except upon application to such appellate division, after notice to the secretary of the commission on discipline. The commission on discipline and/or any member thereof may issue subpoenas and administer oaths pursuant to section sixty-one of the public officers' law in connection with any hearing or investigation under this article and it shall be the duty of such commission to issue subpoenas at the request of and upon behalf of the defense. Said commission on discipline shall not be bound by the laws of evidence in the conduct of its proceedings, but the determination shall be founded upon sufficient legal evidence to sustain the same. The attorney-general shall designate a deputy attorney-general to attend on and advise said commission whenever such service is asked by said commission. For each day that such deputy attorney-general shall be so engaged in behalf of said commission, he shall be paid by said commission a per diem fee of not less than ten dollars. All fees, fines and penalties and forfeitures of bail and other monies that accrue in the prosecution of unlicensed practitioners hereunder and/or paid for registration fees hereunder, shall be paid to the treasurer of the said commission on discipline and from the proceeds thereof the said commission shall defray, as far as the same is sufficient, the expenses of the said commission, the expenses of the regents in printing and distributing the lists of physicians as required by this article, and the expenses of the attorney-general in the prosecution of unlicensed practitioners, and the legislature shall appropriate any unexpended balances returned to the state treasurer by the department of education which were paid to the department of education under this article, to the treasurer of said commission for the expenses of said commission. Said commission, through its said treasurer, shall report any unexpended balance of such monies so paid to the commission remaining in his hands on June thirtieth of each year to the state treasurer, and on and after December thirty-first, nineteen hundred and twenty-eight, and said day each year thereafter, shall return such unexpended balance existing at such time to the state treasurer.

6 Any controversy between two or more physicians; or between a physician or physicians and another person, which said parties to such controversy agree to submit to arbitration, may be submitted in writing to said commission on discipline, who may in their discretion act as arbitrators in said controversy, and the decision of said commission upon such arbitration shall be final, and where the same orders the payment of a sum of money same may be docketed as a judgment of a court of record and enforced as such judgment, provided the terms of the arbitration include such provision.

7 The treasurer of said commission shall furnish a bond approved by the chairman of the

commission in such reasonable sum as the chairman shall fix for the faithful performance of his duties.

8 The commission shall have power to employ such clerical and stenographic help as may be necessary to transact its business and to fix the salaries of such employees and shall have power also to fix a salary for its treasurer.

9 The chief judge of the court of appeals may remove any member of said commission from office who shall have been found guilty, after due hearing, of malfeasance in office or neglect of duty.

10 No member of the commission shall participate in any way in the determination of any charges in which he may be either a witness as to facts or an accused, nor in any case where the parties, complainant or accused, are related to him by consanguinity or affinity within the sixth degree. The degree shall be ascertained by ascending from the commissioner to the common ancestor and descending to the party, counting a degree for each person in both lines, including the member of the commission and the party and excluding the common ancestor.

11 Should, for any reason, three or more members of the commission be disqualified from participating in the decision of any case, or be for other reason unable to participate therein, their places may be temporarily filled for the purpose of determining the case to be heard by the remaining members of the commission nominating twice the number of candidates for such vacancy from whom there shall be selected, after notice to the respective parties, the necessary number of members to constitute a quorum. A quorum of said commission shall consist of six members.

12 Said commission shall have power to make such rules and regulations for the conduct of its business as it shall deem necessary, provided such rules and regulations do not conflict with any of the provisions of this article.

13 The proceedings of said commission shall, before the filing of its final judgment or decision, be secret.

14 The said commission shall have power, where a proceeding has been dismissed, either on the merits or otherwise, to relieve the accused from any possible odium that may attach by reason of the making of charges against him, by such public exoneration as it shall see fit to make if requested by the accused so to do.

Section 11 That if any clause, sentence, paragraph or part of this act shall for any reason be adjudged by any court of competent jurisdiction to be invalid, such judgment shall not affect, impair or invalidate the remainder of said act, but shall be confined in its operation to the clause, sentence, paragraph or part thereof directly involved in the controversy in which such judgment shall have been rendered.

Section 12 This act shall take effect imme-

## SUFFOLK COUNTY MEDICAL SOCIETY

The one hundred and nineteenth annual meeting of the Suffolk County Medical Society was held on Thursday, October 29th, in Riverhead. The President, Dr. George H. Schenck, presided, and 33 members and 6 visitors were present.

Dr. Schenck read the annual presidential address in which he reviewed the activities of the Society during the past year. He mentioned the original work of the special committee on hospital management, as being of great practical value to the four general hospitals of the county. He described the courses in pediatrics which have been conducted as a part of the State Medical Society. He also made a plea for the adoption of the practice of Periodic Health Examinations and stated that he himself knew of five hundred dollars worth of corrective work that had come to himself and another doctor as the result of examinations made by the Life Extension Institute.

Dr. W. H. Ross, Chairman of the Legislative Committee of the County Society and First Vice-President of the State Medical Society, described the general features of the new Practice of Medicine bill. On motion the meeting voted unanimously to approve the bill.

Dr. Guy H. Turrell reported about the Monthly News Letter of the Society, and said that its cost is approximately \$300 annually, which is nearly three dollars per member. He outlined plans for reporting the meetings of the staffs of the four general hospitals of the County and of the four regional medical societies which center about the four hospitals. The News Letter has become so useful to the members that no one questioned the wisdom of continuing its publication.

Dr. Turrell also made a report as Chairman of the Committee on Public Health, and said that the Committee had consulted Dr. Mortimer Raynor, Superintendent of the Kings Park State Hospital, about instituting a course of psychiatric lectures for general practitioners. He said that the care of the insane was the principal item of expense of the State Government, and that the staffs of some of the State hospitals were conducting mental hygiene clinics for the care of incipient cases and those on parole, with the view of preventing the development or recurrence of the disease. He said that a further step that was needed was that physicians in general practice should be taught the fundamentals of psychiatry, for nearly all insane cases consult their doctors for insomnia, nervousness, and other mild manifestations of mental abnormalities.

Dr. Raynor presented an outline of a course of nine lectures and offered to give the courses in the Kings Park Hospital to physicians in the vicinity. On motion the plan of the proposed course was approved, and the Committee on

Public Health was authorized to make arrangements for giving the courses. Dr. Turrell later reported that six doctors present at the meeting said they would attend the course.

Dr. Turrell further reported that a few articles of a public health nature had been prepared and sent to the local newspapers through the cooperation of the County Tuberculosis Committee. Accounts of the meetings of the County Society had been published in this way.

Dr. E. P. Kolb, Superintendent of the Suffolk County Tuberculosis Sanatorium, described the course in tuberculosis which he was conducting at the Sanatorium, and said that one class of six had completed the course and another class had started.

The death of Dr. M. B. Heyman, Superintendent of the Wards Island State Hospital and president of this Society in 1909, was announced, and the Secretary was instructed to write Mrs. Heyman an informal letter of remembrance.

A Committee consisting of Drs. Terrell, Hulse and Loper was appointed to make arrangements for a dinner to commemorate the fiftieth anniversary of the graduation in medicine of Dr. E. S. Moore, of Bay Shore, and Dr. C. C. Miles of Greenport.

The following officers were elected for the year 1926:

President, J. S. Ames, Babylon  
Vice-President, Frank Overton, Patchogue  
Secretary, E. P. Kolb, Holtsville  
Assistant Secretary, W. A. Hulse, Bay Shore.  
Treasurer, David Hallock, Southampton  
Censors, John H. Nugent, A. G. Terrell, David Edwards

Delegates to the State Medical Society, Frank Overton and W. H. Ross

Alternates, David Edwards and George H. Schenck.

The members dined together in the Griffin House, and then reconvened for the scientific session. The guest and principal speaker was Dr. William St. Lawrence, 950 Park Avenue, New York, who spoke on the Administration of Diphtheria Toxin-antitoxin, and of the new serum for the prevention and cure of scarlet fever. Dr. St. Lawrence is a clear and forceful speaker, and is available for pediatric talks and clinics elsewhere.

Dr. Frank Overton gave a brief demonstration of "Wiggly" ankles among school children, and the exercises to stiffen the joints and prevent flat feet. The object of the demonstration was to show how easily the condition could be detected and how the physical trainers in the public schools could give effective exercises to correct the condition.

- complete the rolls and for a mechanism for keeping them thereafter complete

It is provided that a certificate of endorsement of license shall then be issued to each registrant and that the possession of such certificate shall be recognized as prima facie evidence of licensure, and a failure to produce it on proper demand penalized

The Attorney General of the State is instructed to assume the enforcement of the Act but it is provided that he shall not interfere in processes already initiated by District Attorneys in counties of over 500,000 population

The practice without a license is declared prima facie evidence of negligence in civil suits arising from damage sustained as a result of such practice

Misconduct of these admitted to practice—the Profession of Medicine has from time immemorial exacted adherence to a high code of ethics which it is able to maintain among honorable members of the profession. It lacks the mechanism to reach and discipline the men who are beyond the code of honor

The Board of Regents is now given power to revoke or suspend license to practice, but other measures seem desirable, indeed necessary

A body analogous to the Grievance Committee

of the Bar Association is needed if this important work is to be done

This Act provided for such a commission of discipline of the physicians to be nominated by the medical societies of the State, to be appointed by the Chief Justice of the Court of Appeals and to function under a method described without pa

"This commission shall have jurisdiction to hear and determine all charges against duly licensed physicians of this state for violation of the provisions of section one hundred and seventy-four hereof, and shall, upon the finding of such practitioner guilty, have jurisdiction to revoke and annul his license, annul his registration, suspend him from practice or reprimand or otherwise discipline him"

The details of the provisions for the establishment of this body are contained in the Proposed Amendment to the Medical Practice Act which is herewith submitted

On motion duly seconded and carried, the Council approved the work of the Committee and extended the Committee its sincere thanks for the work that it had done

There being no further business, the meeting adjourned at 11 P M

DANIEL S DOUGHERTY,  
Secretary

## BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society was held at Hollywood Gardens, 896 Prospect Avenue, on October 21, 1925. The President, Dr Jacobs, called the meeting to order at 9 P M

Election of candidates being in order, it was moved and carried that the Secretary be instructed to cast one ballot for the following applicants for membership

Nathaniel Jay Gould, Saul Schlossman

Reports of Committees being called for, Dr Eichler, for the Committee on Revision of the By-Laws, reported that the Committee had completed its work and suggested that a special meeting be called to consider and adopt the By-Laws

Dr Friedman, for the Committee on Public Health, reported with special reference to the proposed Periodic Health Examinations

Dr Podvin, for the Bulletin Committee, urged more general cooperation on the part of the members, and requested suggestions or articles for publication in *The Bulletin*

Dr Lukin, Chairman of the Committee on Medical Economics, introduced the following Resolutions

"In view of the fact that the report of the Cornell Clinic for the years 1921-1924 contains unfair references to the medical profession, contains exaggerated self-laudation, and through its review by the lay newspapers serves only

as an advertising medium for that Clinic, and

"Whereas the individual medical man is deprived of the use of advertising through State and National codes of ethics,

"BE IT THEREFORE RESOLVED, That the Bronx County Medical Society declare said report unfair and unethical and that the analysis of the report in question as it appeared in our October *Bulletin*, together with a copy of these Resolutions, be transmitted to the proper authorities for action"

These Resolutions were referred to the Committee on Minors.

Under New Business, the President appealed to the membership for suggestions in regard to the meeting room and the proposed new building; and also suggested that *The Bulletin* be used as a medium for expressing the opinions of the members

Scientific Program—Diagnosis and Treatment of Diseases of the Gall Bladder, David Riesman

Discussion by Philip Eichler, Alexander Goldman, Henry Roth, William Weinberger, Milton R Bookman, Seymour Basch, L M Kahn and J Lewis Amster. Dr Riesman closed the discussion

It was moved that a vote of thanks be extended to Dr Riesman. This motion was unanimously carried, and the President expressed the appreciation of the Society to Dr Riesman

## MEDICAL SOCIETY OF THE COUNTY OF SARATOGA

The annual meeting of the Medical Society of the County of Saratoga was held October 30, 1925, at the Haynes House, Ballston, Spa

Following a luncheon the following scientific program was presented

Dr T Frederick Doescher of Albany, on "Gastric and Duodenal Ulcer, The Medical Treatment" Frederick T Drescher, M D, Albany

"The Surgical Treatment of Gastric and Duodenal Ulcer" E. MacD Stanton, M D, Schenectady

The application of Dr James F Roohan, having been approved by the Board of Censors, motion made that the Secretary be instructed to cast one ballot This was done and Dr Roohan was declared elected

A memoriam to Dr Amos Walter Thompson was next read by Dr Carl Comstock

Motion made and seconded that a copy be sent to Mrs Thompson and a copy be spread on the minutes of the meeting Carried

The Report of the Committee on Post-Graduate Instruction was next presented

Motion made and seconded that it be accepted. Carried

Motion made and seconded that the matter of medical advertisement be left on the table until the next meeting The Secretary was instructed

to write the American Medical Association concerning E F Trieffinger

Motion made and seconded that the President appoint a Nominating Committee Carried

The President appointed Drs Frank J Sherman, Carl R Comstock and William Van Doren

The Nominating Committee presented the following nominations for officers for the ensuing year

President, Dr Earl H King, Saratoga Springs

Vice-President, Dr Arthur W Johnson, Mechanicville

Secretary, Dr Ralph Baker Post, Ballston Spa

Treasurer, Dr John B Ledlie, Saratoga Springs

Censors Drs Merrit E Van Aernem, Saratoga Springs, Walter C Crombie, Mechanicville, George H Fish, Saratoga Springs

Motion made and seconded that the Secretary be instructed to cast one ballot.

This was done and the officers were declared elected

Motion made and seconded that the present By-Law in regard to annual dues be changed to read five dollars per year instead of two dollars Carried

---

## ANNUAL INDUSTRIAL SAFETY CONGRESS

The Ninth Annual Industrial Safety Congress and Exhibit of the New York State Department of Labor will be held in Syracuse, with the headquarters at the Hotel Onondaga on November 30, December 1st, 2nd and 3rd

The safety in industry problem in the State of New York is an important one as judged by the fact that the number of reported industrial accidents for the year ended June 30th, 1925, broke all records, being more than three hundred and seventy-four thousand, not to mention the suffering and general economic loss which this entailed The loss to the people in the State in dollars alone amounted to about seventy millions

To meet this problem, men prominent in all of the branches of industry and also in the professions connected with industry will be present Addresses and carefully prepared scientific papers dealing with industrial safety in its various phases

will comprise the greater part of the program, but no less important will be the participation of the medical profession in the meeting this year

In the first place, the New York State Society of Industrial Medicine will hold its annual meeting in conjunction with the congress, and will assist in every way to make the congress successful This meeting will take place on December 2nd, at 9 30 A M, in the Hiawatha Room of the Onondaga Hotel In the evening of December 2, at the same place at 8 P M, a special session will be held dealing with the surgery of industry

On December 3rd, at 9 30 A M, the morning will be devoted to rehabilitation, and on the afternoon of December 3rd, at 2 P M, the medical session will be devoted to the reading of papers on industrial hygiene The Medical Society of the State of New York is prominently represented on the program

## MEDICAL SOCIETY OF THE COUNTY OF WASHINGTON

The annual meeting of the Medical Society of the County of Washington was held at Hudson Falls, October 6, 1925

The President, Dr Byrnes, called the meeting to order at 11 A M

Members present Byrnes, Prescott, Banker, Paris, Park, Pashley, Cuthbert, Hulsebosch, Oatman, Huntington, Blackfan, Leonard, Munson, Rogers, Stillman, Fortune, Casey, Heath, Tillotson, Holmes

Visitors Henry L K Shaw, M D, of Albany, E DuB Elliott, M D, of Glens Falls

The minutes of the last meeting were read and approved

The President appointed Drs Pashley, Park and Munson as a nominating committee, and the following officers were nominated and elected

President, M A Rogers, M D, Vice-President, Charles A Prescott, M D, Secretary, Silas J Banker, M D, Treasurer, Russel C Paris, M D Censors Byron C Tillotson, Chairman, Edward W Joslin, Stanley T Fortune Committee on Legislation Walter A Leonard, George M Stillman, Harry S Blackfan Delegate to State Society J Leonard Byrnes

A letter was read from Dr Shaw, Chairman of the Committee on Legislation of the State Society, suggesting that the aid of laymen, through the National Association, called the Association for Medical Progress, be employed in our work before the Legislature

A resolution was passed that the President appoint a committee of members representing the different towns of the county to solicit members for this laymen association

The President appointed B C Tillotson, J T Park, A E Falkenbury, M A Rogers, R E LaGrange, H S Blackfan, W S Bennett, Z V D Orton

The Board of Censors reported one registration—Dr H Warren Johnson, of Cambridge, and George Goodell, practicing in Hartford, not registered

Dr Munson presented a paper on "Anterior Poliomyelitis," giving the present views and treatment

Dr Munson presented the following idea relative to the phase of rural practice

I The doctor who is the only physician in the town feels that he is responsible for those who may be sick, and since he has no one with whom to leave his practice he will not leave for any post-graduate work

II He feels that from lack of opportunity to see new work and to study other methods, he is going backwards and rusting out

III The living facilities as such are fairly good The amount of money that the rural practitioner makes, in most instances, is satisfactory but there is no opportunity for recreation or sport Briefly, these are the outstanding drawbacks to rural practice

If it were possible for the Rockefeller Foundation or the Commonwealth Fund, or some similar organization to create a board of relief, one or two or more doctors who have had rural practice, who are physically able and understand the psychology of country practice, who might relieve the general practitioner in the country and let him go to some medical center and do six weeks' post-graduate, at the same time giving him an opportunity for theatres, ball games, etc.

The discussion which followed showed a decided unanimity of opinion that the idea was a good one and that it merited more detailed study

### AFTERNOON SESSION

Dr Shaw explained the object and reason for having laymen help in the legislative work, and the members were all in favor of giving it a trial

Dr Leonard reported for the Tuberculosis Committee and offered a resolution that the committee be discharged and a Committee on Public Health be appointed to take over their work and also prenatal work Passed

The President presented a resolution that the Society go on record as favoring the addition of prenatal work to the tuberculosis work, and an increased appropriation be asked from the Board of Supervisors to carry this out

The President presented an address on Mitral Stenosis, which was very interesting and instructive

It was voted that the Semi-Annual Meeting be held at Fort Edward

The Society then adjourned to the rooms of the Washington County Tuberculosis Clinic, where Dr Shaw gave a very interesting talk on Infant Feeding, illustrated with five undernourished infants and also a number of children from five to eight years old

The matter of post-graduate lectures was left to the Comitia Minora, with a suggestion that they confer with the Warren County Society asking them to join us in this matter

# THE DAILY PRESS

When one reads a newspaper with a medical eye, he is likely to find many articles which come within the range of a physician's professional thought. The New York Herald Tribune of October 28 contains several articles dealing with conditions in which a physician is directly interested:

The very first article on the front page is a long account of a thrilling rescue of the crew of a sinking ship in mid-ocean. What has that got to do with the practice of medicine? The calm coordination of effort by both the endangered crew and the rescuers through long hours of watchful effort is duplicated daily in the practice of every doctor. Panic and cowardice, and wild hysteria are exhibited in the sick room as frequently as on a sinking ship, and more frequently than exhibitions of disabling fear, the doctor finds quiet demonstrations of faith and devotion, of fatiguing service, of self control and of constancy and of gratitude.

Bravery and cowardice, calmness and hysterics are found among the crews of endangered ships, about as often as in the families of the sick, for these qualities are traits of character, and are brought out by any grave emergency when life is threatened, be it in a storm at sea or during the course of a critical fever at a bedside.

In these days of hired attendants, the older doctors like to recall the mother or grandmother, who in her small community was indispensable in every emergency. No one could be born or meet the shadow of death except she was there to calm the distracted household and see that the right thing was always done. She was the exemplification of good sense and devotion,—and wherever she was, there was a radiance of both faith and good works. She embodied the spirit of the Master who calmed the raging seas of perplexing fear, and directed the efforts of the distracted household into efficient channels. She was the Captain of the lifeboat in every time of storm in her community.

The second item in the Herald Tribune of special interest to doctors described the action of the coal dealers of New York City in offering 250,000 tons of soft coal to retail buyers in order to relieve the shortage of fuel, due to the strike among the miners of hard coal. The City Department of Health had already voted the temporary suspension of the rules against burning soft coal. The action of the coal dealers followed what the newspapers called a "threat" that the city would buy the coal and distribute it at about eight dollars a ton, if the coal dealers did not provide the stocks and sell them at a low margin of profit.

The Queens County Grand Jury received dozens of complaints from residents who could not get coal, and it handed up a presentment citing the serious menace to public health, resulting from the coal strike. This and public sentiment generally led the City authorities in all departments, from the lawyers in the Mayor's office to the doctors in the health and hospital departments, to unite in concerted action to meet a grave emergency.

Public officials can always find reasons for either delay or action as they choose. They can wind themselves helpless with red tape, or they can cut its folds, and can quote the lawbooks as the justification of their action.

Why are officials eager to ascribe an emergency health condition to the coal strike, and are often slow to act in still more important health matters? The answer is two-fold, first, the lack of fuel produces immediate discomfort, and second, the cold affects every person. Sick babies are rather rare, smallpox is seldom seen, and when unclean milk produces an epidemic in a community, it is soon forgotten. But cold and poor cooking make everybody aware of a severe coal shortage, and at once there goes up an insistent demand for relief.

But after all, the people and the public officials are even more helpless to prevent the coal shortage than they are to prevent smallpox, and to secure pure supplies of milk and water. It is probable that health matters are handled with greater efficiency than almost any other branch of public work.

In a third item which was of interest to the doctors described the 300 odd replies received in response to an advertisement for a "real servant," who was not afraid of hard work. Only five replied sneeringly and objected to what they called the harsh requirements of being expected to work and give such service as the household might require.

The servant problem is much like the situation regarding the nurse. Some doctors would probably be surprised to find how many trained nurses still retain the old-fashioned ideas of whole-souled service, who are not clock-gazers, who will sit at table with a "practical" nurse, and who will even share a room with a probationer. The number of these devoted nurses extends into the thousands, but the demand for their services far exceeds the supply.

When householders are able to secure devoted help, then physicians also will be able to secure devoted nurses whose chief aim is to take good care of the patients in distinction from their disease.

## THE PRESENT STATUS OF SURGERY FOR BENIGN ULCER OF THE STOMACH AND DUODENUM\*

By CHARLES H PECK, M.D

NEW YORK CITY

THE surgery of benign ulcer has been the topic of so many recent papers and discussions that it would seem as though the subject must be thoroughly exhausted. Nevertheless wide differences of opinion still exist between surgeon and physician and especially between surgeons, as to the indications for operation and the choice of procedure.

There is perhaps less controversy between internist and surgeon as to the cases in need of operative treatment than there is between surgeons as to what shall be done when the abdomen is opened and the ulcer demonstrated.

As the pathology, prognosis and operative indications in chronic duodenal ulcer differ widely from those of chronic gastric ulcer, the two groups should be considered separately. Acute perforation in either group calls for special consideration and will not be included in this communication.

*Chronic Duodenal Ulcer*—For convenience of study it is well to divide chronic duodenal ulcer into groups based upon the pathologic changes present. While this grouping may be varied greatly by different operators, the following will answer our purpose.

1 Small, single, anterior wall ulcers, without narrowing of the lumen or fixation of the duodenum, nor encroachment on the pylorus.

2 Chronic indurated ulcers, without obstruction or hemorrhage, single or multiple.

3 Chronic penetrating ulcer, with sealed perforation, fixation of the duodenum and often an inflammatory mass.

4 Duodenal stricture, or so called pyloric stenosis, with retention of food and dilated stomach.

5 Bleeding ulcer.

*Group One*—May often be treated satisfactorily by local excision without gastro-enteros-

tomy, as practised by Judd and Rankin, or by the Horsley operation, or by Finney's pyloroplasty in the course of which the ulcer is excised.

We have had a moderate number of cases treated by local excision and by the Horsley method, with satisfactory result and are impressed with the simplicity of the procedure in suitable cases. Our experience is too limited and recent, however, to enable us to speak confidently of late results. Horsley himself admits recurrence of symptoms and secondary operation in some of his own cases, and I know of at least one Finney operation which had to be followed a year or so later by gastro-enterostomy. Of all duodenal ulcers, the percentage which fall in this group is relatively small.

*Groups Two and Three*—Chronic ulcer without stenosis or hemorrhage constitute the great majority of all duodenal ulcers.

We believe that gastro-enterostomy is the best primary operation for these cases, whether chronic perforation or inflammatory mass is present or not.

The argument that gastro-enterostomy is ineffective if there is no obstruction we believe to be fallacious.

Whatever the real cause of duodenal ulcer may be, mechanical and chemical influences play a distinct rôle. The ulcers nearly all develop within  $1\frac{1}{2}$  inches of the pylorus, the part of the duodenal wall which receives the impact of acrid stomach content, pumped intermittently through the pylorus in spurts, as though by the piston of a syringe. This content is often a strong chemical irritant, not altogether dependent on the amount of hydrochloric acid present for its corrosive action and quite capable of causing injury to the delicate duodenal mucous membrane.

The great frequency of this lesion in young men, the group perhaps most likely to be careless or reckless about the combinations of food and

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 13, 1925.

# BOOK REVIEWS

**LANG'S GERMAN-ENGLISH DICTIONARY OF TERMS USED IN MEDICINE AND THE ALLIED SCIENCES** Edited and Revised by MILTON K. MEYERS, M.D. Third Edition, enlarged Octavo of 613 pages Phila., P. Blakiston's Son & Co, 1924 Cloth, \$7.00

This is the third and enlarged edition of a German-English medical dictionary, which is found to be, not only complete and very well arranged, but because of its thoroughness, will prove of inestimable value to him who writes as well as to him who may from time to time simply refer to the German literature in the course of reading.

Perhaps a few illustrations may not be amiss, in order that the reviewer's contention may be more readily emphasized. For example, in connection with the term "Lippen—lip, labium, edge, crest, border," one finds following this sixty-one terms with lip as part of so many compound words.

Under the term "Bandwurm—Tape-worm," the text gives the various types of the parasite both in the original as well as the English equivalent, after that follow various compound words with "Band-wurm" as the basis, e. g., "Bandwurm-Ei (Ovum of tapeworm)", "Bandwurm-Ghied (proglottis of tapeworm)", etc.

In connection with the term "Leber" (liver), the book uses enough compound words to occupy three and a half full length columns (half page).

One other outstanding feature of this book is the fact that it avoids the usual mistake so frequently found in books of its kind, namely that of translating for example—"Arthrodie—ball and socket joint" (instead of simply—arthrodia), "Colopexie—suspension of the colon by sutures" (instead of simply—colopexia), etc.

Owing to the great variety and number of words herein translated and defined, the translator of German publications as well as the casual reader of the German literature will find this Glossary of great help, time saving, as well as instructive.

HARRY APPEL

**THE PHYSIOLOGY OF MIND** An Interpretation Based on Biological, Morphological, Physical and Chemical Considerations By FRANCIS X. DERCUM, A.M. M.D., Ph.D. Second edition, reset. Octavo of 287 pages Phila. and London, W. B. Saunders Co, 1925 Cloth, \$3.50

This book is largely a discussion of certain fundamental considerations underlying the study of the mind. The style is quite readable and the subject matter is interesting. As is customary in his writings, the author seizes upon every opportunity to "let slip the dogs of war" upon Freudism.

FREDERIC DAMRAU

**THE INHERITANCE OF MENTAL DISEASES** By ABRAHAM MEYERSON Octavo of 336 pages Baltimore, Williams and Wilkins Co, 1925 Cloth, \$5.00

After an exhaustive study of the literature the author has attempted to evaluate the importance of the various factors entering into the hereditary transmission of mental disease. The reader who is in search of information on this subject will here find a considerable mass of data clearly expressed and conservatively interpreted. An excellent bibliography is appended.

FREDERIC DAMRAU

**PRINCIPALS OF SURGERY FOR NURSES** By M. S. WOOLF, M.A., B.Sc., M.R.C.S. (Eng.), L.R.C.P. (Lond.) Octavo of 350 pages, illustrated Phila. and London, W. B. Saunders Co, 1925 Cloth, \$3.00

This is indeed the most complete and yet simple treatise on Surgery for Nurses that we have encountered. It cannot but achieve its object as outlined in the preface, "nurses have desired something less than a medical students' text-book and something more than a work on technic,—whereas they have often surgical procedure well in hand, the principles on which it is founded have remained obscure to them."

The more prominent surgical conditions are treated in simple, plain language, and at the end of each chapter a very complete summary taken from Hey Groves' Synopsis allows one to more thoroughly cover the subject.

With the present tendency to a shorter term of service in training schools, this very compact little volume should become a popular text-book with student nurses, and will be greatly appreciated by all those who, like the author, undertake to teach Surgery to nurses.

W. V. P.

**PRACTICAL HISTOLOGY** By HENRY ERDMANN RADASCH, M.Sc., M.D. Second Edition. Revised and Enlarged, 12mo of 621 pages, with 333 illustrations Phila., P. Blakiston's Son and Co, 1924 Cloth, \$5.00

A second edition of this volume is an amplified and improved model of the first. The subject matter is handled in a capable and concise manner. The illustrations are ample and clear.

Although this book cannot replace the older standard works in this subject, it will serve as a useful guide and addendum to the student.

MAX LEDERER.

**TOXICOLOGY OR THE EFFECTS OF POISONS** By FRANK P. UNDERHILL, Ph.D. 12mo of 292 pages Phila., P. Blakiston's Son and Co, 1924 Cloth, \$2.25

This is a book based upon a course of lectures given before the medical students of Yale Medical School. The title does not indicate the full scope of the book. It includes a description of a pretty full list of drugs and chemicals having a poisonous effect, with fatal dose, symptoms, post mortem appearances and treatment. The poisons are grouped into the usual Inorganic, Metallic, Poisonous Gases, Alkaloidal Poisons, and a large group of unclassified Organic Poisons. This last group occupying about 100 of the 263 pages deals mostly with well known drug which in excessive doses exert an untoward or poisonous action. While most of this information can be found in any of the larger text-books of pharmacology and therapeutics, it is here brought together under the heading of poisons.

It seems to the reviewer that the directions for treatment are not as definite and specific as they ought to be. No emergency strikes greater terror in the mind of a physician than acute poisoning. Such directions as "empty the stomach," "give stimulants and demulcent drinks" seem too general to satisfy the demand for immediate help in a desperate emergency like a case of acute poisoning.

The information is reliable and up to date, and well adapted to the use of students in following a course of lectures.

E. H. B.

other cases operated upon in which the original operation was done elsewhere are well and free from symptoms

Lewisohn recently reported a series of 92 cases of gastro-enterostomy from the Mt Sinai Clinic in which 16 per cent developed jejunal ulcer proved by secondary operation and an additional 17 per cent had symptoms indicating jejunal ulcer, not proven by operation. We do not believe that such a high incidence is of common occurrence, as our own experience and that of most clinics puts the percentage at less than 3 per cent.

The question of post-operative morbidity after simple gastro-enterostomy is the subject of much discussion, and there is much pessimism expressed which we do not share. We have taken pains to follow these patients and in our series of the cases traced 98 in number, including the 4 jejunal ulcers, 89 or 90.8 per cent or 91.7 per cent are permanently relieved and free from gastric symptoms.

**Summary**—1 Surgical treatment of duodenal ulcer, should be advised only after medical treatment has failed to give relief, when symptoms relapse after temporary improvement, or when X-ray examination shows definite stenosis or penetrating ulcer.

2 The operation of choice should be simple gastro-enterostomy. Radical resection should be reserved for cases with severe hemorrhage, those with recurrent symptoms after simple operations, or cases of jejunal ulcer.

3 A lasting clinical cure may be expected in 85-90 per cent of cases treated by simple gastro-enterostomy.

**Chronic Gastric Ulcer**—Presents problems which differ radically from those of duodenal ulcer. It is a generally accepted principle that gastric ulcers must be excised or removed in some way, whenever it is possible. These ulcers do not heal after simple gastro-enterostomy as frequently as duodenal ulcers, symptoms are apt to persist, and in addition there is always the fear that malignancy may be present at the time of operation or may develop in the ulcer area later.

The frequency with which cancer is implanted on benign ulcer has long been a matter of dispute, the estimates varying from the 68 per cent of the earlier Mayo Clinic reports, down to 2 or 3 per cent, or even zero as a few radical disponents claim.

It is at least a well known fact that it is impossible to exclude the presence of cancer implantation, by gross examination at the time of operation, and a pretty general belief that it may develop later in an appreciable number of cases whatever the exact percentage may be.

The three chief operative procedures are

1 Local excision of the ulcer with or without gastro-enterostomy

2 Cautery puncture, with or without gastro-enterostomy

3 Partial gastrectomy or pylorotomy

Local excision may be supplemented by the use of the cautery and gastro-enterostomy should always be added, as the resulting cicatrix necessarily distorts the stomach to some extent, and interferes with its normal peristaltic action.

For ulcers of moderate size, especially those near the middle of the lesser curvature this is our method of choice and it gives excellent results.

In ulcers high up, near the cardia, where excision is difficult or impossible, cautery puncture, with gastro-enterostomy offers a satisfactory method.

Pylorotomy or partial gastrectomy should be done for ulcers close to the pylorus, and for the larger ulcers in the pyloric third of the stomach. It is preferred by many surgeons for the majority of all gastric ulcers, instead of local excision.

The particular method varies according to the fancy of the surgeon. We prefer the Billroth II when the ulcer is not too high up or too large. When more than half of the stomach must be resected the Mayo-Polya method is probably the best, the ante-colic type being apparently more in favor now than the anastomosis through the transverse meso-colon. It is the method of choice with many surgeons, even in the lower resections.

Modifications of the Billroth I, i. e., excision followed by gastro-duodenal anastomosis have had a recent wave of popularity, due in part perhaps to the brilliant work of Von Haberer at Innsbruck.

Finney has recently advocated an end to side gastro-duodenal anastomosis, which may be used when the duodenum can be sufficiently mobilized.

Free mobilization of the duodenum is essential in any gastro-duodenal anastomosis, and is not always easily obtained.

Chronic perforation with adhesion to the pancreas or posterior structures may make mobilization of the stomach and resection extremely difficult, and sometimes impossible.

**Hour Glass Stomach**, the result of ulcer calls for special procedures among which are

1 Gastro-gastrostomy between the two pouches

2 Gastro-plasty of the type of Finney pyloroplasty

3 Gastro-enterostomy

4 Partial gastrectomy

5 Trans-gastric resection

We have had satisfactory results with all of these methods except gastro-enterostomy.

We have had 79 cases of gastric ulcer in our series, with eight deaths, a mortality of 10 per cent.

drink introduced into their stomachs is a suggestive fact

When the ulcer is once formed, it is constantly irritated by the impact of chyme and by the action of the pyloric sphincter, and has little encouragement to heal.

Gastro-enterostomy lessens the irritant character of the stomach content, partly by diminishing the acidity, and partly by lessening the time in which it is churned about in the stomach

It also lessens greatly the amount which passes through the pylorus, and especially the force of the impact of that which does pass

We believe that these influences may be interpreted as in part, at least, explaining why the ulcers heal so often and so promptly after simple gastro-enterostomy and why the clinical results are so good in a high percentage of cases so treated

That in a small percentage of cases, healing fails, and symptoms persist or recur, we freely admit, but we believe that this happens in less than 15 per cent, even when the cases are unselected and the severe pathologic types are included in the study. We do not believe that radical pylorotomy or partial gastrectomy should be the choice for the primary operation in the types of ulcer above considered, in spite of the widespread teaching to the contrary and the popular attempt to discredit gastro-enterostomy now prevalent

*Group Four*—That cases with duodenal stricture or so-called pyloric stenosis are best treated by gastro-enterostomy is generally conceded

The patients are often starved, dehydrated and emaciated to the last degree, and we have been obliged repeatedly to resort to transfusion, hypodermoclysis, and operation under local anaesthesia, to avoid immediate fatality. The change in expression, gain in vitality and general comfort, smoothing out of wrinkles and gain in weight which comes after food and fluid reaches the intestine where it can be assimilated in sufficient quantity, picture some of the most brilliant and satisfactory results met with in abdominal surgery

*Group Five*—Bleeding ulcer occurs most frequently in those situated on the posterior wall or against the head of the pancreas, and in deep, penetrating ulcers. Hemorrhage occurs in about 14 per cent of all cases and is always a serious complication. We have seen patients die of duodenal hemorrhage before any operation could be performed, and others so exsanguinated that preliminary blood transfusion alone made operation possible

Gastro-enterostomy is not a guarantee against recurrence of hemorrhage which may prove fatal and excision of the ulcer is desirable if the condition of the patient will permit

We have performed pylorotomy several times

for bleeding ulcer, but on the other hand have been obliged to be content with simple gastro-enterostomy many times when the risk of the radical operation seemed too great for the exsanguinated and debilitated patient. Transfusion in moderate amount is a great aid in these cases. I was once forced reluctantly to operate upon a woman of 74 years of age for repeated duodenal hemorrhage after refusing to do so for fifteen months

Simple gastro-enterostomy was followed by a complete cessation of both the hemorrhages and the ulcer symptoms and she is alive and well, able to eat what she chooses at the age of 84

Hemorrhage is apt to occur in cases in which extensive induration and fixation of the duodenum would make radical operation extremely hazardous or impossible. A two-stage operation, gastro-enterostomy first, followed by resection 10 to 14 days later may be indicated, especially if hemorrhage recurs after the gastro-enterostomy. The inflammatory induration often melts away and makes secondary resection easier and safer than it would have been at the primary operation

In many cases of hemorrhage it is wiser to defer operative treatment, depending on rest, sedatives, fluid diet and small, repeated transfusions to control the bleeding

This plan is often successful, permitting the election of a later time for operation when the patient has recovered from the immediate effects of hemorrhage and is a better operative risk

We have had 228 cases of chronic duodenal ulcer, 144 since 1915 and 74 previously reported with 19 deaths, a total mortality of 0.88 per cent

Comparatively few of these deaths have been directly attributable to the operation per se, as many of them have been in elderly people with complicating conditions. Of three deaths occurring in 22 cases since January 1st, 1924, one was in a feeble woman of 60 in whom cholecystectomy was done in addition to the gastro-enterostomy, an error in operative judgment

Nine deaths in the series were due to post-operative pneumonia, three to uraemia in old nephritics, one to diabetic coma, one to cerebral thrombosis and one to pulmonary embolism

Three deaths were attributable to the operation per se, one from vicious circle, one from acute stomach dilatation, and in one there was peritonitis following breaking open of the wound

There was no post-operative hemorrhage in the series, and only three cases of vicious circle, two of which recovered after secondary operations and are now well, after nine years and five years respectively

There have been only five cases of jejunal ulcer in the series as far as we have been able to trace, all proven by secondary operation. Four recovered and one died, two of the recovered cases still have symptoms and two are well. Two

tegrity of the organs of sense, of the centripetal nerves, of the conduction paths and terminal stations within the nerve centres, and of the associative mechanisms that combine the activities of the central stations with one another. Sense-stimulation, conduction of centripetal influences, perception, memory revival, association of ideas—all are parts of the process of knowing. Disorders of sensation, of conduction, of attention, of perception, of memory or of association limit or distort the data upon which identification, orientation, imagination, reasoning and judgment depend.

Eyes, ears, nose, taste-buds, touch spots, pain spots, and temperature spots in the skin, as well as the sensory nerve-beginnings in the muscles, bones, joints and viscera, must be intact if sensory stimuli are to start the centripetal impulses that are necessary or desirable for orientation, for the gaining of knowledge of the world outside, or for warnings of abnormal processes going on inside the body. A school-boy may appear to be stupid because of a severe hyperopic astigmatism, a tendency to isolation may be traceable to the embarrassment of bilateral labyrinthine deafness, a sensation of pain may be the first warning of the onset of a pleurisy, an appendicitis, or an attack of gout.

Or, again, if conduction be interfered with in peripheral nerves, in the spinal cord, or in the brain, *anaesthesias*, or *paraesthesias*, of corresponding distribution will be demonstrable. Thus, vision may become defective because of an optic neuritis, a bladder may become distended because a patient with tabetic degeneration in the spinal cord may not have the normal sensation that accompanies overfilling; numbness in the fingers and toes may be the first intimation of the cord changes accompanying or preceding the development of a pernicious anaemia, or complete loss of sensation of one-half of the body may point to a destructive lesion of the posterior part of the occipital lobe of the internal capsule.

Irritations of sensory conduction paths may excite remarkable psychic reactions in the form of sensations of *pain*, for example, the neuralgias of peripheral nerve origin (like sciatica, lumbago and tic douloureux) or the lightning pains of tabes due to irritations of the posterior roots of the spinal nerves and their intramedullary continuations. Many of the *common complaints* for which patients consult physicians consist of subjective sensations due to irritations of sense organs or of sensory conduction paths, in addition to the neuralgias just referred to. I need mention only headache, dizziness, sore throat, otalgia, palpitation, angina pectoris, stitch in the side, epigastralgia, nausea, hunger pain, colic, tenderness, dysmenorrhoea, arthralgia, osteoscopic pain, and myalgia—all of which are psychical reactions to mechanical or chemical stimulations of nerves. In this domain especially, every general and every

special practitioner of medicine has learned to evaluate psychic factors for diagnosis.

Disturbances of sense perception and identification are also common in general medical experience. Since normal perception depends upon the fusion of sensations with revived memories of similar sensations previously experienced, disturbances here may have their cause in abnormal sensation, in faulty memory, or in imperfect assimilation of sensation to revived experience. Here belong, on the one hand, the *sense-deceptions* that we know as hallucinations and illusions, and, on the other, the *sensory aphasias and agnosias*. You will all recall alcoholics (in post-Volstead as well as in pre-Volstead days) who saw many small, black, moving objects where you could see none, each of you has doubtless heard schizophrenics give reports of the visions they saw and the voices they heard, though healthy persons present failed to corroborate the occurrence of such sights or sounds, or you may have noticed with alarm the illusion of the paranoiac who interpreted some harmless sound as a threat. Failure to recognize or to identify perceptions even though sensation be unimpaired is a peculiar psychic disturbance, sometimes spoken of as mental anaesthesia. If the failure of recognition has to deal with symbolic things, like words, figures, musical notes or gestures it is called sensory aphasia, of which inability to read (*alexia*) and inability to recognize the meaning of words heard (*word deafness*) are well-known examples, but if the failure of identification be of non-symbolic things it is called sensory asymblia or agnosia (*visual, acoustic or tactile*). These psychic disturbances are nearly always due to severe organic lesions—vascular, neoplastic, or inflammatory.

The sensory aphasias and the agnosias just referred to are, in part, *memory defects*, due to injury or destruction of local areas in which certain memory traces (*engrams*) are stored. We distinguish these *partial amnesias* from the more general amnesias (or losses of memory) and *paramnesias* (or perversions of memory).

In *general amnesia*, all memories both old and recent may be impaired. Thus in advanced atherosclerosis of the cerebral arteries or in destructive processes of the cerebral cortex such as occur in dementia paralytica there may be inability to recall either the experiences of earlier or of later life. When school memories can be easily revived but recent events cannot be remembered, the memory difficulty may be due to loss of the ability to increase or supplement the store of memories (so-called "*recording faculty*") and this incapacity may in turn depend upon a disorder of attention, either an inability to direct the thought to a definite task (*hypovigility*), or to maintain this direction in the presence of intercurrent stimuli (*hypotenacity*).

Among the *paramnesias*, or perversions of

# PSYCHIC FACTORS IN GENERAL MEDICAL DIAGNOSIS\*

By LEWELLYS F BARKER, M D

BALTIMORE, MD

## WHAT MEDICAL DIAGNOSIS IS

**B**Y DIAGNOSIS we mean a thorough knowledge of the human being that we study. Diagnosis is, therefore, an ideal which we attempt to approach, the acquisition of complete knowledge regarding any living organism being beyond our powers. More particularly, in medical diagnosis we strive to ascertain in how far a given human being is healthy or ill and the reasons therefor, by which in turn we mean in how far he is (as a whole and in each of his parts) capable or incapable of making adequate responses to the physical and psychological influences of the environment in which he lives, and why. Adequacy of responsivity indicates health, whereas inadequacy of responsivity indicates disease or anomaly. Health and disease are conditioned, it is the task of diagnosis to attempt to determine the conditioning factors in given instances.

## WHAT WE MEAN BY PSYCHIC FACTORS

Human beings are extremely complex living organisms that result from the interplay of surroundings with fertilized egg-cells. Their potentialities of structure and function lie in the germ-cells in which they start, which of the potentialities come to actual development depends, as biologists now agree, upon the influences that act upon the germ cells and their derivatives during intrauterine and post natal life.

The functional activities of human beings are usually subdivided into somatic and psychic, though it is by no means easy sharply to separate the one set of functions from the other. Without entering into any discussion of this topic, I shall here class as "psychic" not only everything that occurs in consciousness, but also all those functions that, occurring unconsciously, may in other circumstances become conscious. My paper has to deal then with the significance of the conscious (or potentially conscious) phenomena discoverable in studies directed toward the determination of the degree of adequacy, or inadequacy, of responsivity of human constitutions to environmental influences. In how far are these psychic factors (conscious or unconscious) of importance for medical diagnosis, that is to say, for the determination of the existence of healthy states on the one hand or of anomalous or diseased states on the other?

It would seem that in man, as in the higher animals generally, the psychic functions have evolved from the simpler instinctive tendencies. In each instinctive tendency, three constituents

are discernible — (1) a knowing or cognitive constituent, (2) a feeling or affective constituent and (3) a striving or conative constituent. The sum total of the human psychisms pertaining to knowing we speak of as *cognition* and *intellect*, of those pertaining to feeling and emotion as *affectivity*, and of those pertaining to striving as *will* or *conation*. A human personality is then a complex of cognition, affectivity and conation, the two latter are often considered together as composing *character* (as contrasted with cognition and intellect). The *intellect* seems to be an instrument that has been evolved in the interest of character, in other words, in order better to satisfy our desires by our activities, it has become necessary increasingly to know. Adequate responsivity of a human being to physical and social pressures in a changing environment depends then upon suitable cognitive, affective and conative functioning. Obviously, therefore, for good medical diagnosis, that is to say for satisfactory recognition of adequacy or inadequacy of responsivity in the persons physicians study, ability to investigate the psychic functions upon which responsivity and irresponsivity largely depend would seem to be indispensable. And similarly, therapy, the task of which is to endeavor to make irresponsible organisms more adequately responsive, can scarcely hope to be successful if, concentrating upon physical defects alone, it fail to give attention to the psychic factors of adjustment. Both soma and psyche require accurate and painstaking investigation in medical diagnosis and adequate attention in medical therapy, he who would be a skillful diagnostician or an expert therapist dare not neglect either the somatic or the psychic deviations from normal functioning.

## THE COGNITIVE AND INTELLECTUAL FUNCTIONS AND MEDICAL DIAGNOSIS

### (The Functions of Knowing)

Comprehensively to deal with the cognitive, affective and conative factors that are important for general medical diagnosis would require the writing of a large treatise, in a brief paper one must be content merely to sketch the topic in broad outlines.

Cognition depends upon the ability to receive impressions from the external world through sense-organs, to conduct these impressions through peripheral nerves to central nervous organs, to combine these impressions with one another and with revived impressions of previous experiences, and to form perceptions and judgments that are consonant with objective reality. In other words, intellectual functioning in an adequately responsive person presupposes the in-

\* Read at the annual meeting of the Medical Society of the State of New York at Syracuse, May 13 1925

of 'suniness' or of 'blueness'. And the more episodic emotional states of delight or of disgust or joy or of grief, of love or of hatred, of anxiety or of peace, of satisfaction or of dissatisfaction, of anger or of humility, of fear or of courage, and so on through the whole gamut or the emotions, are also familiar to each of us.

No two persons exhibit precisely the same affective reactions, and the affectivity of a single person may fluctuate greatly at different times and seasons. What we call *character*, *temperament* and *disposition* are largely determined by affectivity. The strength and depth of the ethical affects account for the differences between a good and a bad character. A person of sanguine temperament exhibits labile affects whereas one of phlegmatic temperament manifests steadier and sometimes deeper feeling and emotion. Similarly, irritability or placidity of disposition are terms indicative of affective tendencies, due either to constitution or to situation. Nothing else in another person influences us as much as the affective states that he exhibits, we feel them and instinctively react to them, that is why they are largely regulative of our social relationships.

Moreover, thought and behavior are markedly dependent upon desires and moods, for 'intellect' and 'will' work at the behest of the 'affects', it is natural for every one to try to satisfy his desires, to gain pleasures and to avoid discomforts. Thus the attitude assumed by the person as a whole is an expression of the affective states he experiences. And the latter appear to depend in large part upon neuro-endocrine make-up and the ways in which the neuro-endocrine apparatus reacts to the internal and the external environment.

In our patients we meet with the most remarkable disturbances in the domain of the affects—pathological intensification, pathological protraction, pathological irradiation and displacement. The outspoken disturbances are familiar to every layman as well as to every practitioner. In the melancholic patient we observe every gradation of depression from marked "downheartedness" to the deepest sadness and gloom, he suffers continual "mental torture," so severe that he often prefers to die rather than to live, he has lost all interest in persons and in things except in his sufferings, he harbors ideas of self depreciation of self blame, of poverty and of sin, he thinks and moves slowly, his attitude is stooped, the angles of his mouth hang down, and his skin is wrinkled and dessicated so that he looks older than his years. In the manic patient we observe the affective opposite, namely every gradation of *euphoria* from simple preternatural cheerfulness and enjoyment of the world and of life to highly pathological excitement and elation; he is ecstatically happy, interested in everything, but very distractible, turning from

one object of interest to another with great rapidity because of the superficiality and acceleration of his associations. Nothing is an effort for him, he feels no fatigue and he accordingly manifests outspoken pressure of activity. His ideas are expansive and grandiose, he feels superior, indeed greatly overestimates his own value and position and makes claims that sometimes bring him into violent conflict with those about him, he is prone to be erotic and venturesome, his thoughts, his speech and his movements are accentuated. He stands erect with smiling face, glistening eyes and aggressive attitude and his skin is smooth and turgid so that he looks younger than his years. These two contrasting syndromes of pathological affectivity—the *melancholic* and the *manic*—are met with in their purest forms in the manic-depressive psychosis where one may alternate with the other. Milder cyclothymic states are, however, very frequent and their true nature often goes unrecognized. In my opinion, many of the patients who suffer from recurrent nervous breakdowns (spoken of as recurrent neurasthenia or recurrent psycho-neurotic state) really belong in this group, for if the family history be investigated a family tendency to elation-depression syndromes, or to suicides, will often be discovered. Many of these patients with milder symptoms in their depressed periods seek relief from their discomforts by consulting internists, surgeons and medical and surgical specialists rather than neurologists or psychiatrists and submit themselves to all sorts of therapeutic regimes in the hope of relieving what they call their "toxic condition." Particularly in hypo-chondriacal depressions has this been true. With the best intentions appendices, tonsils and teeth are removed, gall bladders are excised, supposed ureteral strictures are dilated, sphincters are stretched, nasal operations are performed, antra are washed out, high colonic irrigations are given, hysterectomies are performed, autogenous vaccines are prepared and administered, foreign proteins are injected, orthopedic appliances are adjusted, special diets are ordered, uniglandular and multiglandular endocrine products are fed, hydrotherapy, mechanotherapy, climatotherapy, radiotherapy and psychotherapy are tried—all without avail. In time, the depression runs its course, the inhibition symptoms disappear to be succeeded by normal affectivity or by mild elation, the patient becomes what he calls "well" whether at the time of change he be in the hands of a regular practitioner or of a quack. Whoever happens to be in attendance upon him when the change occurs may be accredited with the "cure," though sometimes the patient will attribute the "cure" to some special measure that he himself has thought of and applied just precedent to the change!

The affective states of elation and of depression are by no means confined to the groups of

memory, may be mentioned those peculiar states in which patients describe wholly imaginary events as though they were memories of actual experiences, here belong the confabulations of hysterical patients and the pseudo-remiscences of persons suffering from the polyneuritic psychosis of Korsakoff. Not far removed from these disturbances are the pathological lying exhibited by certain degenerates and the pseudologia fantastica of certain egoistic psychopaths who give free rein to their fancies in the concoction and relation of dramatic tales of their alleged experiences.

Disturbances of *association* and of *thought* are much more abstruse phenomena than those hitherto considered, for the normal associative processes and normal intelligence are the most complex functions that occur anywhere in nature. I shall not attempt to discuss them at length, but will mention merely a few of the more striking pathological conditions of interest for general medical diagnosis. Associations are combinations and arrangements of psychisms (sensations, perceptions, revived memories) into larger units, they are essential parts of the processes of thinking, of imagining, and of judgment-formation, they are the foundation of the *intelligence*. Associations may be pathologically accelerated or retarded. A good example of such *acceleration* is to be observed in the flight of ideas and exaggerated distractibility of manic and hypomanic states, I have a hyperthyroid patient under observation just now whose thoughts come so rapidly that, in trying to give expression to them, they (to use her own words) "stumble over one another." The opposite state, pathological retardation of associations, is characteristic of many morbid depressions, you have all observed the slow, labored talk and the apparent poverty of ideas of melancholics.

Another disturbance of association is the appearance of *bizarre links* in a chain of thought difficult for a normal person to understand. Thus in dementia praecox the successive components of the expressed thoughts may be so peculiar as to puzzle completely the examining physician as to their origin, they resemble the unintelligible associations that may occur in one's dreams. Every gradation may be met with from mild distortion to the most peculiar condensations, displacements and symbolisms, the severest disturbances give rise to "incoherence."

It is probable that abnormalities of association are responsible, at least in part, for the origin of a variety of *pathological ideas*, such as (1) the imperative ideas or obsessions, (2) the exaggerated ideas of hypochondriasis and of premonitional states, and (3) the true delusions.

Patients suffering from compulsion-neuroses (psychasthenia) may be bothered much by *obsessions*, thus they may think that their hands

are contaminated, that they will carry infections to others, or that they will injure someone with a sharp instrument. Though it is realized fully that these thoughts are absurd, nevertheless, they constantly recur and annoy the patients. Combined with various phobias, with pathological impulses, with indecision, and with feelings of unreality, the patients on whom they intrude may be severely tortured by these imperative ideas.

The *exaggerated ideas* that occur in hypochondriacs and in those who experience "premonitions" are not recognized by those who harbor them as intruders in consciousness or as being absurd, on the contrary, they are looked upon as true expressions of the inner personality. Such exaggerated ideas stand very close to the pathological ideas that we designate as true delusions.

A *delusion* differs from an error in that the latter may be corrected by a new and enlightening experience, whereas the former is created by an inner (affective) need, not by an accidental fault of logic, and is likely to persist as long as the abnormal affective state that gives rise to it persists, despite all efforts to correct it by instruction or by enlargement of experience. Thus, no one can convince the patient that his delusion is a false idea, for he completely lacks what is called "disease-insight." In melancholic states, delusions of unworthiness, of sin, and of poverty are dominant, in manic states, delusions of power and of grandeur are characteristic, and in paranoid states, ideas of reference and delusions of persecution are unmistakable symptoms. In all these delusions the disturbances are affective as well as cognitive, they are probably determined as much by feeling-tone and emotion as by abnormalities of the associative processes.

## THE AFFECTIVE FUNCTIONS AND MEDICAL DIAGNOSIS

### (The Functions of Feeling)

When we turn to the affective functions we enter a domain of the very greatest importance for general medical diagnosis, since on the one hand nearly all diseased states of the body cause some disturbance of the feeling of well-being and, on the other, the disturbances of affectivity in certain disorders that are primarily nervous or mental may mislead practitioners who are not sufficiently familiar with them to suspect the existence of diseases of the heart, of the gastrointestinal tract, or of other special domains of the soma.

By the affective functions (or *affectivity*) we understand the psychic phenomena known as feeling-tones, moods and emotions. Every cognitive psychism, be it a sensation, or an idea, is accompanied by a positive or a negative *feeling-tone*—that is to say, it is tinged by pleasure or displeasure. Every one knows, too, what is meant by *moods*—more or less prolonged states

more than the practitioner of medicine needs to be tolerant of the vagaries of human behavior, or to possess the insight that will enable him to understand and to explain the weak or the perverse "will"?

If your patience were not already exhausted, I should be tempted to discuss certain *disturbances of the personality as a whole* (e.g., alternating personality, splittings of the personality disintegration of the personality and depersonalization) as well as certain *disturbances of the consciousness as a whole* (e.g., sleep disorders, hypnosis, comas, tuper, twilight states and deliria) and their relations to medical diagnosis. But I forbear

I hope that the matters already presented may suffice to convince practitioners of the importance of investigating psychical as well as physical factors in their patients when they wish to make comprehensive diagnostic studies. May the time soon come when medical schools will pay more attention to psychology and psychiatry, as was urged by Dr. Matzinger at your meeting last year<sup>1</sup>. And may I express the hope, also, that more physicians will combine with interested laymen in forwarding campaigns of Mental Hygiene in the communities in which they live. Such campaigns are fully as important as many other preventive measures for the promotion of the health and the welfare of our people.

## INFECTIONS OF THE URINARY TRACT IN CHILDREN \*

By HENRY G. BUGBEE, M.D.

NEW YORK CITY

IN the Second Edition of Holt's "Textbook on Pediatrics" (Published in 1902), he states that infections of the urinary tract in children consist of cystitis, pyelitis or pyelocystitis, the latter often associated with a nephritis, that they are found largely in female children, the colon bacillus being the offending organism, gaining entrance to the urethra from napkins soiled with feces coming in contact with the vulva with an ascending infection of the urethra, bladder, and, possibly, along the ureter to the kidney. Primary kidney infections are mentioned as an accompaniment of certain infectious diseases or caused by the irritation of renal calculi or associated with tuberculosis or tumors. He states that occasional infections in boys may bring up the question of the possibility of a blood infection or direct extension from intestines to the bladder. Holt further says that these infections often accompany diarrheal diseases.

Since that time, infections of the urinary tract in children have been regarded on this basis by the majority of pediatricians.

During the past five years, however, attention has been focused on these conditions and more accurate observations made through study by urologists and by the combined observations of urologists and pediatricians. Scientific investigations have been carried out by both specialists and the consensus of opinion, at the present time, is that the urinary tract in infants and children is subject to the same type of infections as in adults and that the mode of infection is probably the same.

There are apparently two general types of infections in children, namely, those without urinary stasis and those in which a definite lesion is

present which interferes with complete drainage.

In the first type of infection, the organism most often found is the colon bacillus which has been produced in large numbers in the intestinal tract due to some intestinal disturbance, and which is supplied to the kidneys through the blood stream.

It is not my purpose to enter into an elaborate discussion of the theories advanced for the particular route of infection, but clinical and experimental data point overwhelmingly to this mode of infection in children which is unquestionably true in adults. My own observations, as well as those of most other urologists, would suggest that these lesions in children are quite similar to those in adults.

Holt noted the absence of acute vaginitis in female children who were supposed to be infected from the outside, and I have noted in the majority of children very little distress referable to the urethra. Furthermore with the subsidence of the kidney infection, treatment is seldom necessary to clear up the lower urinary tract.

Coccus infections are most often secondary to focal infections somewhere in the body—the tonsils often being primarily the focus.

The lesions found in both colon bacillus and coccus infections of the kidney point to the theory that the infections are a pyelonephritis rather than a true pyelitis.

Helmholz has shown in his experiments that the kidney seldom, if ever, filters through bacteria without some change taking place in the kidney parenchyma.

The milder types of kidney infection, due to the colon bacillus, may cause comparatively little systemic reaction, few of the symptoms being associated with the kidney until after pus and bacteria have been discovered in the urine.

\* Read before the Connecticut State Medical Society at Yale University, September 23, 1925.

patients just mentioned, they are sometimes met with as episodes in other disorders, notably in schizophrenia and in organic psychoses like dementia paralytica, great care should therefore be taken to make a thorough study of each case before deciding upon its nosological position and relationships.

Time will not permit of further discussion of disorders of affectivity. I shall therefore only refer without comment to the *pathological irritability* met with in manics, in epileptics, in paralytics and in imbeciles, to the *apathy*, the *negativism* and the *affective ambivalence* so often observed in schizophrenics, and to the *affective defects and perversions* encountered in psychoneurotics, in psychopathic personalities, in juvenile offenders, in delinquents and in criminals.

### THE CONATIVE FUNCTIONS AND MEDICAL DIAGNOSIS

#### (The Functions of Striving)

Thus far I have dealt chiefly with two main psychic functions, "thinking" and "feeling"—that is to say with the cognitive and affective activities, it is now time to refer, if but briefly, to the third main psychic function, "striving"—that is to say, to the *conative* functions. Here we have to deal with the relations of human volition (or "will") and human action ("behavior") to medical diagnosis, in other words, in how far can a study of a man's *decisions* and of a man's *conduct* be useful in evaluating adequacy and inadequacy of responsivity, which we have agreed to regard as criteria of healthy and of diseased or anomalous states?

Normal human organisms strive to attain certain goals. Among their aims are self-preservation, race continuation, the acquisition and dissemination of knowledge, social intercourse with their fellows, the creation and the appreciation of beauty, and "right" conduct. They have the "will to live," "the will to power," the "will to co-habit," the "will to work," the "will to play," the "will to associate," and still other "wills." Nutritive impulses, activity impulses, sexual impulses, social impulses, aesthetic impulses and ethical impulses are present in all healthy persons. In a theoretically normal life, a life of adequate responsivity, all of these strivings would be represented in a balanced way. In actual life this ideal is rarely, if ever, closely approximated. And among our patients we meet with the most diverse deviations from normally balanced strivings, we encounter manifold defects, exaggerations, and perversions of those strivings. Even in healthy persons the existence of multiple impulses necessitates what we call "choice", when one impulse is favored, others must, temporarily, be suppressed.

"Choice" or "decision" involves the whole personality, though it depends chiefly upon the existing state of affectivity, an action appears when

one or another impulse has attained to domination. As Bleuler says, "We do what we wish because we wish what we do." And our doing and our wishing appear to be the functional resultants of the interaction of our inherited equipment with a long series of influences (substances and forces) in our environment. If this view be correct, two corollaries are obvious: (1) fully to understand the behavior of a human being one would require a complete knowledge of his heredity and of his environment and of the interactions between the two, and (2) a knowledge of the behavior of a human being should throw light upon the structure and functions of his body and mind and should give clues to the recognition of the inheritance factors and of the environmental influences upon which structure and function depend. Obviously, then, the study of the conative functions (the wishes, the decisions, and the acts) of patients and of their conditionings must be of great importance for the higher forms of medical diagnosis. That is why internists and neuropsychiatrists, especially, lay such great stress upon the *anamnesis* and inquire fully into *hereditary predispositions* and prenatal and postnatal *environmental situations*. Dietary experiences, sexual experiences, education, economic struggles, work and recreation, aesthetic experiences, ethical attitudes, mental conflicts—all may be of importance. And the history of the behavior of the person through all these experiences together with his behavior when under the physician's observation will, taken with the facts in the family history, yield the data upon which medical judgment regarding the "springs" of behavior must be based.

The science of human behavior is as yet but in its beginnings, but modern neurology and psychiatry are making valiant contributions to it. The study of the decisions and of the acts of psychoneurotics, of psychotics, of delinquents and of criminals has not only been of great help in the medical diagnosis of abnormal mental states but has already thrown much light upon the psychological processes of healthy people. No physician familiar with the motor aphasia and apraxias of organic brain diseases, the indecision of psychasthenics, the conative conflicts of psychoneurotics, the facilitated conduct of manics, the inhibited behavior of melancholics, the stereotyped movements and attitudes, the command-automatisms, the grimaces and the mannerisms of schizophrenics, the sex-perversions and other behavior-anomalies of psychopathic personalities, the restricted aims and achievements of oligophrenics, and the anti-social acts of criminals and delinquents will be likely to deny the significance of studies of the conative functions for the understanding of the patients with whose welfare he is entrusted. Such studies are most valuable, too, because of their influence on the physician's own "total view of life", for who

more than the practitioner of medicine needs to be tolerant of the vagaries of human behavior, or to possess the insight that will enable him to understand and to explain the weak or the perverse "will"?

If your patience were not already exhausted, I should be tempted to discuss certain *disturbances of the personality as a whole* (e.g., alternating personality, splittings of the personality disintegration of the personality and depersonalization) as well as certain *disturbances of the consciousness as a whole* (e.g., sleep disorders, hypnosis, comas, tupor, twilight states and deliria) and their relations to medical diagnosis. But I forbear

I hope that the matters already presented may suffice to convince practitioners of the importance of investigating psychical as well as physical factors in their patients when they wish to make comprehensive diagnostic studies. May the time soon come when medical schools will pay more attention to psychology and psychiatry, as was urged by Dr. Matzinger at your meeting last year! And may I express the hope, also, that more physicians will combine with interested laymen in forwarding campaigns of Mental Hygiene in the communities in which they live. Such campaigns are fully as important as many other preventive measures for the promotion of the health and the welfare of our people.

## INFECTIONS OF THE URINARY TRACT IN CHILDREN \*

By HENRY G. BUGBEE, M.D.

NEW YORK CITY

IN the Second Edition of Holt's "Textbook on Pediatrics" (Published in 1902), he states that infections of the urinary tract in children consist of cystitis, pyelitis or pyelocystitis, the latter often associated with a nephritis, that they are found largely in female children, the colon bacillus being the offending organism, gaining entrance to the urethra from napkins soiled with feces coming in contact with the vulva with an ascending infection of the urethra, bladder, and, possibly, along the ureter to the kidney. Primary kidney infections are mentioned as an accompaniment of certain infectious diseases or caused by the irritation of renal calculi or associated with tuberculosis or tumors. He states that occasional infections in boys may bring up the question of the possibility of a blood infection or direct extension from intestines to the bladder. Holt further says that these infections often accompany diarrheal diseases.

Since that time, infections of the urinary tract in children have been regarded on this basis by the majority of pediatricians.

During the past five years, however, attention has been focused on these conditions and more accurate observations made through study by urologists and by the combined observations of urologists and pediatricians. Scientific investigations have been carried out by both specialists and the consensus of opinion, at the present time, is that the urinary tract in infants and children is subject to the same type of infections as in adults and that the mode of infection is probably the same.

There are apparently two general types of infections in children, namely, those without urinary stasis and those in which a definite lesion is

present which interferes with complete drainage. In the first type of infection, the organism most often found is the colon bacillus which has been produced in large numbers in the intestinal tract due to some intestinal disturbance, and which is supplied to the kidneys through the blood stream.

It is not my purpose to enter into an elaborate discussion of the theories advanced for the particular route of infection, but clinical and experimental data point overwhelmingly to this mode of infection in children which is unquestionably true in adults. My own observations, as well as those of most other urologists, would suggest that these lesions in children are quite similar to those in adults.

Holt noted the absence of acute vaginitis in female children who were supposed to be infected from the outside, and I have noted in the majority of children very little distress referable to the urethra. Furthermore with the subsidence of the kidney infection, treatment is seldom necessary to clear up the lower urinary tract.

Coccus infections are most often secondary to focal infections somewhere in the body—the tonsils often being primarily the focus.

The lesions found in both colon bacillus and coccus infections of the kidney point to the theory that the infections are a pyelonephritis rather than a true pyelitis.

Helmholz has shown in his experiments that the kidney seldom, if ever, filters through bacteria without some change taking place in the kidney parenchyma.

The milder types of kidney infection, due to the colon bacillus, may cause comparatively little systemic reaction, few of the symptoms being associated with the kidney until after pus and bacteria have been discovered in the urine.

\* Read before the Connecticut State Medical Society at Yale University, September 23, 1925.

These infections, as a rule, clear up readily, are treated by the family physician or pediatrician, and are seldom seen by the urologist.

The acute infections of the kidney, that I have seen in consultation with pediatricians have been of the severe type, the children often being critically ill with a temperature up to 105, rapid pulse, often vomiting, abdominal distension, etc. A large percentage of children with this type of infection that I have seen have been suffering from an intestinal disorder. Often when these children were first seen the urine was clear. Attention may have been fixed upon the kidney by localized tenderness. These cases often clear up readily after a thorough clearing out of the intestinal tract with colonic irrigations and a flushing of the kidneys.

In this regard, water is the most important drug and should be given in as large quantities as the child can take. Early in the infection, alkalis seem to be beneficial by stimulating the kidney activity and by changing the reaction of the urine, thereby possibly inhibiting the growth of the colon bacilli.

If the temperature and local signs do not disappear readily, there is no contra-indication to cystoscopic investigation of the urinary tract. At the present time with the instruments that are made especially for children, it is quite as possible after dilating the urethra, to pass a cystoscope into the bladder of a child as of an adult. Pediatricians are often loathe to have these small patients cystoscoped until they have seen that it is possible to carry out this manipulation without damage to the urethra or without severe reaction, but it has been my experience of late that I have been the one to hold out on the manipulation until other methods of treatment have been tried.

After the cystoscope has been introduced into bladder, it is no more difficult to investigate the bladder and catheterize the ureters in a child than in an adult.

In severe acute infections, even in the absence of an obstruction in the ureter, the passing of a ureteral catheter and irrigation of one or both kidney pelves may establish drainage from the kidney tubules and the symptoms subside almost immediately. I have, on a number of occasions, left a ureteral catheter in a child from three to eight days and irrigated the kidney several times a day.

In one child of ten, entering the hospital with a temperature of 106, and with a question of diagnosis of acute pyelonephritis or acute appendicitis, this treatment resulted in an immediate disappearance of all of her symptoms. At the end of eight days, her urine was entirely clear.

When the kidneys are acting freely, it may be well to change the reaction of the urine to acid by stopping the administration of alkalis, sub-

stituting benzoic acid if necessary, and then giving Urotropin. Methylene blue is often useful as it does not cause congestion of the renal tubules, and has a slight inhibitory effect upon the colon bacilli. Hexylresorcinol is still in the experimental stage.

In coccus infections of the kidney, the parenchyma is always involved and often minute abscesses are found throughout the kidney tissue.

In a case observed during the past six months a child of two and a half years entered the hospital with a temperature of 105.2. There was pus in the urine and both kidneys could be palpated, the right being distinctly enlarged and tender. Over a period of ten days I made a cystoscopic examination on three occasions and found small plugs of pus in the urine from the right kidney and the culture showed streptococci. There were a few pus cells in the urine from the left kidney. With each irrigation of the right kidney pelvis, the temperature dropped to a lower level. The physicians in attendance felt that the child was losing ground, and should be operated. At operation the kidney was found enlarged and engorged. The capsule was removed and numerous minute abscesses were found in the kidney parenchyma. These small abscesses were curetted, the kidney was drained and the child recovered.

I have always felt that this child would have done quite as well without the operation. The demonstration of the lesion was interesting, but at the most only an increase of circulation was obtained.

I have not been able to demonstrate cases of colon bacillus infection of the lower urinary tract in children without an infection of one or both kidneys. There are reports of several instances in children in which cultures from the kidneys were negative, while those from the bladder were positive. This has been found in adults.

Often times the kidney specimen is obtained too dilute and in too small a quantity to give a positive culture, while the larger quantity of bladder urine, which is more concentrated, would give a positive culture. If these tests are repeated, however, it is often possible to obtain positive cultures from the kidneys or the kidney infection may have cleared up and the secondary infection of the lower tract persisted.

While the vast majority of acute infections of the urinary tract in children will clear up under medication and general systemic treatment, especially when the gastro-intestinal tract is taken into consideration at the same time, very severe infections that do not clear up at once should have special investigation by means of cystoscopic methods, also, chronic infections that do not clear up through systemic means should be investigated in the same manner. Many of the

latter type of cases that I have seen in consultation have presented a real lesion of the urinary tract which would have made it impossible for the patient to recover under the ordinary methods of treatment

I have done a nephrectomy in several cases of unilateral kidney infection which would not clear up even though drainage from the kidney was entirely satisfactory. These kidneys have invariably shown multiple minute abscesses throughout the parenchyma.

The two most important factors entering into the etiology of infections of the urinary tract are: First, a supply of bacteria to the kidney, and, second, an interference with proper drainage.

In persistent infections of the urinary tract in infants, I have found a lesion which has interfered with drainage so often present, that I cannot speak too emphatically of the wisdom of proper investigation in these cases. The instance of these lesions stimulated me to investigate post-mortem specimens and in conjunction with Dr. Woolstein, Pathologist of the Babies Hospital in New York, we reviewed 4,903 necropsies and found 117 anomalies of the urinary tract, 101 of these infants dying under one year of age. In almost every instance these anomalies had interfered with proper urinary drainage and bacteria which might otherwise have been eliminated without causing symptoms had caused an infection when aided by urinary stasis. These lesions consisted of phimosis, stricture of the urethra, valve formations of the mucous membrane of the urethra and of the mucous membrane of the bladder, producing a flap which

dropped over the vesical orifice or over a ureteral orifice, congenital hypertrophy of the verumontanum, spina-bifida occulta, causing interference with the proper expulsion of urine from the bladder, diverticula of the bladder, strictures and anomalies of the ureter, calculi in the pelvis of the kidney or in the ureter, cystic degeneration of the kidney, redundancy of kidney substance, horseshoe kidneys, rudimentary kidneys, and congenital absence of a kidney, fusion of the kidneys, displacement of one or both kidneys.

A lesion was found in 2½% of all autopsies which gives some idea of the frequency with which anomalies are present. Obviously an infection superimposed upon such a condition would not clear up by ordinary methods of treatment. Only the most careful study of the child and probably only by surgery would it be possible to relieve the condition.

My particular message, therefore, is to impress upon you the fact that the urinary tract in children is subject to the same lesions and pathological processes as in adults, and that in treating obscure abdominal conditions, the possibility of an infection of the urinary tract must be born in mind, that a complete examination of the urinary tract is quite as possible in children as in adults, and that a sterile specimen of urine should always be obtained (which means catheterization in the female child), that the persistence of pyuria, hematuria or abdominal pain should be an indication for such an examination, and only by such means may it be possible to clear up the condition.

## THE INFLUENCE OF SEX UPON THE CONSTITUTIONAL FACTOR IN DISEASE\*

By GEORGE DRAPER, M.D.

NEW YORK CITY

From the Department of the Practice of Medicine, Presbyterian Hospital and Columbia University, New York City

**T**HROUGHOUT the course of investigations at the Constitution Clinic of the Presbyterian Hospital our attention has been drawn increasingly to the influence of sex as a factor in determining individual constitution or total personality. Reference was made to this problem in a previous report,<sup>1</sup> and the purpose of this essay is to develop the subject still further. Ordinarily, one's conception of sex is in terms either of the phenomenon of reproduction or of the psychological confusions which arise from the interplay of the emotions of men and women. The particular aspects of the matter which here concern us are

related more directly to the general biology of sex, and their discussion expresses an effort to draw from clinical medicine some light to help in the exploration of this still obscure portion of the natural history of life.

It has long been known that though sex is almost universally found it does not seem to be a necessary attribute of living things. This is true of many of the lower animal forms, as well as of plants. When sex does appear in the ascending scale of living organisms, it presents the most amazing and varied forms of expression. Parthenogenesis alternating with fertilization in the same species, asexual and sexual cycles, females with actual inclusions of the male elements in her tissues or parasitic upon them, organisms starting

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 12, 1925.

out as one sex which then in the course of growth change to the opposite sex and back again, these are some of the curious mechanisms of reproduction which biologists have shown to exist. But, besides the matter of reproductive mechanism, there remain to be explained the remarkable conditions of hermaphroditism (an organism possessing the gonads of both sexes), pseudo-hermaphroditism (an organism possessing parts of the sex apparatus of both sexes), gynandro-morphism (an organism exhibiting body characters of both sexes, either half and half or in elaborate mosaïque), and the whole question of the secondary sex characters. These last are not limited to the physical habitus, but find equally definite expression in the three other panels of personality (physiology, psychology and possibly also, immunity).

Beyond these phenomena of sex one finds still more complex fields of transmission of characters through what is called the sex linked or sex limited mechanism. Morgan,<sup>2</sup> Davenport,<sup>3</sup> Pearl<sup>4</sup> and many others have written extensively on this subject and described many characters, including disease susceptibilities, which are inherited through the devious paths of sex linkage. Furthermore, the whole question of the determination of sex is an important part of the problem and has been extensively discussed by Doncaster,<sup>5</sup> Wilson,<sup>6</sup> Conklin,<sup>7</sup> Winnwater<sup>8</sup> and others. Then after sex has been determined, the degree to which it differentiates introduces still another factor of importance to clinical medicine. In addition to hereditary forces which influence differentiation, it has been shown that environmental conditions which change the metabolic rate in the embryo,<sup>9</sup> or hormone effects may limit differentiation. Indeed, Lillie<sup>10</sup> believes that the determination of sex is not an "irreversible predestination, but "a quantitative overbalance in the direction of one sex or another" which may be subsequently changed. Notwithstanding the effect of environment, however, the evidence seems to be strong that sex is an inherited character.

Ordinarily, in the higher forms at least, we associate sex entirely with the gonads. From this standpoint testicle and ovary epitomize the sex difference and their hormones determine the form and extent of the secondary sex characters. But there seems to be some evidence that sex may be something more than the presence of a gonad. Steche,<sup>11</sup> for example, has shown in moths by precipitin tests that the bloods of males and females of the same species differ as much as do the bloods of individuals of the same sex of different species. Furthermore, the complete association of gonads and secondary sex characters is not fully established in all forms. It is true that in the vertebrates, Steinach<sup>12</sup> and others have shown by castration and transplantation experiments that the gonads definitely influence second-

ary sex characters. But on the other hand Meisenheimer and Roper<sup>13</sup> have demonstrated that in insects the secondary sex characters are entirely independent of the presence of the sex glands.

In connection with castration experiments, it is interesting to observe that in all species among vertebrates removal of the gonads produces far more extensive effects upon the male than upon the female. Furthermore, the castrated male takes on characters which in many respects are similar to the female. The obvious inference from these facts is that the female is less widely differentiated from the neuter or species type than is the male. This inference is given support by the single case of a true neuter (lacking any gonad tissue) described by Pollard<sup>14</sup>. The individual possessed feminized habitus, sedentary tastes and the rather feeble personality commonly found in male castrates. Laurent,<sup>15</sup> in his book "Les Bisexuels," advances the thought that femaleness is the expression of an arrested species type.

The observations of Jordan<sup>16</sup> on hermaphroditism are interesting in this connection. He believes that the human embryo is originally potentially hermaphroditic and that the definite sex of an individual results from inhibition and, later, suppression of the opposite sex primordium. Just as types of metabolism underlying various characters and activities of the organism become represented in germ cells by parts of chromosomes, so grades of metabolism determining male or female sex are likewise represented. When the metabolism is of the male determining grade, the primordial germ cells differentiate into sperm, when the rate is of female determining grade, ova differentiate from the primordium. This conception receives considerable support from the now well-known fact that the basal metabolic rate at all ages is 2 per cent to 4 per cent higher for males than for females. Furthermore, the probable relationship of different metabolism rates to the sexes is strongly suggested in an ancient observation of biologists which Doncaster<sup>17</sup> reflects in the statement that the egg is large, quiescent and stores up energy. The sperm, on the other hand, is small, actively motile and spends energy. These differences are, in general, characteristic of the sexes in almost all species. Geddes and Thompson<sup>18</sup> have expressed the same thought by saying that femaleness is correlated with preponderant anabolism, maleness with preponderant katabolism.

Obviously, if this increased metabolic rate is a characteristic of maleness, it must be effective very early in the life of the organism. For there seems to be little doubt that sex is established perhaps at the first cell division, if not earlier, in either egg or sperm. Now if sex is thus early established, what happens at puberty? Clinical

experience surely indicates that disease propensities are rearranged at the time of that episode. Is there a change, or merely an intensification of the sex quality throughout, or is there simply a completing of sex by the addition of sperm discharge and ovulation? And at the climacteric, is there a loss of each differential sex quality with a convergence again upon the basic species type?

### CLINICAL SECTION

From these introductory remarks on the biology of sex, we may turn our attention to certain clinical observations which are not without interest in this connection.

In the first place, a study of vital statistics shows clearly that from the start the battle of life goes harder with the male than with the female. Thus the disproportionate chance of survival for males at different periods from fertilization up till the end of the first year<sup>15</sup> is indicated by the following figures<sup>19</sup>

For every 100 female abortions there are 160 male.

For every 100 female still births there are 136 male.

For every 100 female living births there are 106 male.

At the end of the first year for 103 females living there are 100 males.

From then on the sex death rate curves run nearly parallel, with the male rate always slightly greater until the thirty-fifth year when the male rate runs ahead rapidly. For example, the percentage of male or female death rate by ages runs<sup>20</sup>

1 to 14 years	110.5
5 " 9 "	119
10 " 14 "	105.5
15 " 19 "	112.4
20 " 24 "	117.3
25 " 34 "	119.7
35 " 44 "	136.3

In an extensive study of this long-known fact of greater male mortality, Moebius<sup>21</sup> concluded that it depended upon the greater hazards of life to which males were exposed, including alcohol and venery. But a careful consideration of the distribution of disease according to its sex frequency leads one to question the soundness of Moebius' conclusion.

If one reads the paragraph on etiology for each disease in Osler's, or any other good text book of medicine, or, indeed, in the larger systems of medicine, one is struck with the cursory manner in which the bearing of sex on susceptibility is passed over. Furthermore, there are differences in the statements of various authors concerning the sex differences in susceptibility. However, from the text books, systems and census reports the following lists have been made out, showing such differences as are known to exist between the disease potentialities of the sexes.

### MALES

27 Diseases	Preponderance
Pneumonia	5 to 1
C S B Meningitis	Slight
Amoebic dysentery	15 to 1
Polio-myelitis	Slight +
Diabetes	3 to 2
Scurvy	Greatly +
Gastric Ulcer	4 or 5 to 1
Acute pancreatitis	Large majority
Bronchial asthma	More often
Sero fib pleurisy	48 to 1
Pernicious anemia	2 to 1
Lækæmia	More often
Hodgkins	More often
Hæmophilia	100% p
Angina pectoris	6 to 1
Addison's disease (muscle power)	More often
Bantus disease	More often
Alcoholism	6 to 1
Tabes	10 to 1
Paresis	Much more
Progress B Paral.	More often
Erbs dystrophy	More often
Syringomyelia	23 to 1
Cerebral Haem	Greatly +
Sciatica	Greatly +
Paralysis agitans	Greatly +
Pseudohermaph	10 to 1
(2,000 cases)	

### FEMALES

20 Diseases	Preponderance
Diphtheria	Slight +
Influenza	2 to 1
Whooping cough	1.25 to 1
Rheumatic fever	Consid. +
Tonsillitis	Slight +
Pellagra	Slight +
Obesity	Consid. +
Gall stones	3 or 5 to 1
Movable kidney	7 to 1
Chlorosis	100% p
Goitre (exophth)	6 or 8 to 1
Myxoedæmia	6 to 1
Hyperthyroidism	12.5 to 1
Acromegaly	More often
Multiple sclerosis	More often
Continued sclerosis	More often
Korsakoff's syndrome	7 to 1
Chorea	24 to 1
Purpura Haemorrhagica	4 or 5 to 1
Migraine	6 to 1
Raynaud's disease	15 to 1
Arthritis deformans (menopause)	44 to 1
Hysteria	7 to 1

Now it will be observed that diseases of rather different mechanisms appear in the two lists. Thus, males are more susceptible to most infections, especially pneumonia and pleurisy, pancreas and adrenal disease, vascular disease, muscular dystrophies, spinal cord tract disease and blood dyscrasias. With the exception, perhaps, of the infections, these are maladies involving all the mechanism for energy expenditure. Females, on the other hand, besides the interesting and unexplained greater susceptibility to whooping cough, influenza and rheumatic fever, show more susceptibility than the male to the endocrinopathies, diffuse cord lesions and functional nervous disorders, arthritis deformans, gall stones and obesity. In general, this group of diseases involves the protective and energy accumulating mechanisms.

It is also possible to re-group diseases in relation to sex influence in the following manner.

I Diseases in which difference of incidence depends on the greater exposure of the male to all the more hazardous environmental influences. Under this heading may be mentioned injuries, dust exposure diseases (t.b.), pneumonia, typhoid fever, dysentery and nephritis.

II Diseases in which difference of incidence is not so clearly due to greater hazard, for example, whooping cough and cancer, which are considerably more frequent in females, and polio-

out as one sex which then in the course of growth change to the opposite sex and back again, these are some of the curious mechanisms of reproduction which biologists have shown to exist. But, besides the matter of reproductive mechanism, there remain to be explained the remarkable conditions of hermaphroditism (an organism possessing the gonads of both sexes), pseudo-hermaphroditism (an organism possessing parts of the sex apparatus of both sexes), gynandro-morphism (an organism exhibiting body characters of both sexes, either half and half or in elaborate mosaïque), and the whole question of the secondary sex characters. These last are not limited to the physical habitus, but find equally definite expression in the three other panels of personality (physiology, psychology and possibly also, immunity)

Beyond these phenomena of sex one finds the still more complex field of transmission of characters through what is called the sex linked or sex limited mechanism. Morgan,<sup>2</sup> Davenport,<sup>3</sup> Pearl<sup>4</sup> and many others have written extensively on this subject and described many characters, including disease susceptibilities, which are inherited through the devious paths of sex linkage. Furthermore, the whole question of the determination of sex is an important part of the problem and has been extensively discussed by Doncaster,<sup>5</sup> Wilson,<sup>6</sup> Conklin,<sup>7</sup> Winnwater<sup>8</sup> and others. Then after sex has been determined, the degree to which it differentiates introduces still another factor of importance to clinical medicine. In addition to hereditary forces which influence differentiation, it has been shown that environmental conditions which change the metabolic rate in the embryo,<sup>9</sup> or hormone effects may limit differentiation. Indeed, Lillie<sup>10</sup> believes that the determination of sex is not an "irreversible predestination, but "a quantitative overbalance in the direction of one sex or another" which may be subsequently changed. Notwithstanding the effect of environment, however, the evidence seems to be strong that sex is an inherited character.

Ordinarily, in the higher forms at least, we associate sex entirely with the gonads. From this standpoint testicle and ovary epitomize the sex difference and their hormones determine the form and extent of the secondary sex characters. But there seems to be some evidence that sex may be something more than the presence of a gonad. Steche,<sup>11</sup> for example, has shown in moths by precipitin tests that the bloods of males and females of the same species differ as much as do the bloods of individuals of the same sex of different species. Furthermore, the complete association of gonads and secondary sex characters is not fully established in all forms. It is true that in the vertebrates, Steinach<sup>12</sup> and others have shown by castration and transplantation experiments that the gonads definitely influence second-

ary sex characters. But on the other hand Meisenheimer and Roper<sup>13</sup> have demonstrated that in insects the secondary sex characters are entirely independent of the presence of the sex glands.

In connection with castration experiments, it is interesting to observe that in all species among vertebrates removal of the gonads produces far more extensive effects upon the male than upon the female. Furthermore, the castrated male takes on characters which in many respects are similar to the female. The obvious inference from these facts is that the female is less widely differentiated from the neuter or species type than is the male. This inference is given support by the single case of a true neuter (lacking any gonad tissue) described by Pollailon.<sup>14</sup> The individual possessed feminized habitus, sedentary tastes and the rather feeble personality commonly found in male castrates. Laurent,<sup>15</sup> in his book "Les Bisexues," advances the thought that femaleness is the expression of an arrested species type.

The observations of Jordan<sup>16</sup> on hermaphroditism are interesting in this connection. He believes that the human embryo is originally potentially hermaphroditic and that the definite sex of an individual results from inhibition and, later, suppression of the opposite sex primordium. Just as types of metabolism underlying various characters and activities of the organism become represented in germ cells by parts of chromosomes, so grades of metabolism determining male or female sex are likewise represented. When the metabolism is of the male determining grade, the primordial germ cells differentiate into sperm, when the rate is of female determining grade, ova differentiate from the primordium. This conception receives considerable support from the now well-known fact that the basal metabolic rate at all ages is 2 per cent to 4 per cent higher for males than for females. Furthermore, the probable relationship of different metabolism rates to the sexes is strongly suggested in an ancient observation of biologists which Doncaster<sup>17</sup> reflects in the statement that the egg is large, quiescent and stores up energy. The sperm, on the other hand, is small, actively motile and spends energy. These differences are, in general, characteristic of the sexes in almost all species. Geddes and Thompson<sup>18</sup> have expressed the same thought by saying that femaleness is correlated with preponderant anabolism, maleness with preponderant katabolism.

Obviously, if this increased metabolic rate is a characteristic of maleness, it must be effective very early in the life of the organism. For there seems to be little doubt that sex is established perhaps at the first cell division, if not earlier, in either egg or sperm. Now if sex is thus early established, what happens at puberty? Clinical

and type of pseudo-hermaphroditism, or the relationship which such individuals bear to the completed sexes and to the community. However, notwithstanding the extent and the excellence of the observations and descriptions given by these authors, there remains much to be explained about hermaphroditism and pseudo-hermaphroditism in human beings. But entirely outside this group of bi-sexual forms there are still to be found those individuals who, though possessing an adequate reproductive apparatus of one sex, display in certain subtle lines of body contour, facial or manual expression and turns of mind the secondary characters of the other. This type is, of course, best looked upon as analogous to the state of gynandromorphism earlier mentioned as found in birds and insects.

Now, when the distribution of disease between the sexes is considered, and when the morphology and psyche of patients are studied in relation to their diseases, one receives a strong impression that sex is a constitutional factor of fundamental importance in determining disease potentiality. Indeed, in certain diseases this selective susceptibility between the sexes is so definite that one is forced to look upon disease potentially as a secondary sex character, a co-ordinate of physical contour and psychic pattern. It was pointed out that in some of the lower orders, especially the insects, there was no association between the presence or absence of the gonads and the existence of secondary sex characters. But the existence of a very definite, if not causal, relationship of secondary sex characters and gonads in man, has long been known, and within the last decade thoroughly studied by Tandler and Grosz and their host of followers. The former believe that all secondary sex characters are primarily species characters which have been especially modified to hold particular relationship with the genital plan. Consequently, these authors feel that in studying any organ or character the point to be kept in mind is how much of this character expresses species and how much of it is a secondary sex modification.

Their experiments with castrated animals, and their observations on eunuchs and eunuchoids furthermore led them to the conclusion that the bodily and mental changes following castration in each sex do not indicate a change to characters of the opposite sex, but rather that each castrate converges to a common species type with similar characters. Castration, then, according to these authors, results in a prolonged state of unripeness. The epiphyses are held open and, consequently, long bone growth is not checked. Early castration in either sex thus has the dual effect of arresting development and differentiation, but of encouraging growth. The peculiarities exposed as the result of castration are, therefore, considered to be species characters. Now if the effects of low efficiency gonads, as found in

eunuchoids and so-called intermediate sex forms, are to be looked upon as the results of a sort of partial genetic castration, then such individuals of each sex tend toward a common or species type. Consequently, these persons should have the disease potentiality common to their species and not to their weakly indicated sex.

So far as it has been possible to analyze the material which has been collected at the Constitution Clinic it appears that there are three ways in which the sex factor enters in to the relationship between constitution and disease. In the first place, there is the situation wherein both sexes display diminished secondary sex characters and likewise present the eunuchoidal trunk extremity ratio. Thus, for example, both sexes in the pernicious anemia race have shown short trunks and long extremities, the so-called eunuchoidal habits. Their secondary sex characters furthermore have enhanced this picture of gonadal inferiority. But, as Tandler and Grosz have pointed out, this sex differentiation may actually disclose the basic species form common to both sexes. From this the thought arises that without the protection of a fully differentiated sex influence certain idiosyncrasies which carry a predisposition to easy blood destruction and poor hematopoiesis develop pernicious anemia.

The second manner in which the sex factor finds expression is in those diseases which are found much more frequently in one sex than another. Thus, for example, as has been mentioned, gall bladder disease is three or four times more common in women than in men. But in addition to this well-recognized fact, our studies have shown that the males who develop cholelithiasis clearly tend toward the fat avirile type, or may express the feministic trend in the psychic pattern. Furthermore, the male pelvis among gall bladder people is the widest of all males and females, except that of the pernicious anemia females. This pelvic largeness is reflected again in the high bi-iliac-biacromial index of the males of the gall bladder race. From these observations it would seem not unreasonable to suppose that the more completely differentiated individuals are toward maleness or femaleness, the less close should be their predispositions for those diseases in which the sex factor is a determining one. Possibly, when studies of all the panels of personality are completed and correlated it will be found that those individuals of one sex who succumb to a disease chiefly encountered in the opposite sex should exhibit signs of an incomplete differentiation toward their own sex.

The third way in which the sex factor may manifest itself is not as well defined as are the two preceding. Briefly, it appears that when the sex character differences are accounted for, there remain marked differences between the sexes in those morphologic characters which are criteria of species. These latter differences are most

myelitis which shows a definite affinity for the male

III Diseases in which difference of incidence suggests that the sex factor is a true constitutional influence in determining susceptibility

- Endocrine disturbances
- Chronic rheumatic osteo-arthritis, obesity
- Gall bladder disease, ulcer of the stomach, purpura hæmorrhagica
- Korsakoff's syndrome
- Congenital deformities

IV Genetic influences showing through sex linkage The following conditions reported by Laughlin,<sup>22</sup> Davenport<sup>23</sup> and others are dominant in males and recessive in females

- Coloboma
- Color blindness
- Night blindness
- Nystagmus
- Ichthyosis
- Multiple sclerosis
- Gower's muscular atrophy
- Hæmophilia
- Webbed toes

In the light of these observations and those discussed earlier in the paper, it may be of interest to attempt a somewhat more critical analysis of some of the diseases whose incidence differs among the two sexes

**Influenza** Females are affected slightly more often than males, but a significant thing about influenza in females is, on the one hand, its remarkable association with menstruation, and, on the other hand, its devastating effect upon woman during pregnancy

**Diabetes Mellitus** The frequency of diabetes mellitus is somewhat greater in males up to the age of 45, or until maleness begins to wane. From 45 years on females display greater numbers. This would suggest a susceptibility factor in femaleness. But if the two sexes converge after the climacteric toward a common species type, why should waning maleness result in greater resistance to the disease than waning femaleness? An answer to this question may be found in the theory which Emerson<sup>24</sup> has advanced that hard physical work is a protection. The muscular indolence of women, as well as their overfeeding after 45, is a well-known situation and may account for their greater susceptibility

**Gall Bladder** Male 942, female 2,478 per 100,000 of population. This is practically the reverse of the situation found in gastric and duodenal ulcer. While it might be possible to ascribe the far greater incidence among females to their habits of over-eating and insufficient exercise, there are certain reasons for believing that other factors are at work, for the males who develop gall bladder disease, especially cholelithiasis, present definite feminized trends in various

phases of their constitutional plan. Thus, in addition to an actual pelvis width, as well as a pelvic shoulder breadth index which is greater than that found in males of all other disease races, there are also feministic traits of gesture and psyche. Such males may be perfectly adequate sires, but none the less present definite gynandromorphic mosaics

**Congenital Malformations** It is interesting that all forms of congenital malformation are more common in males than in females. Is this because the female, being nearer the species types, is less highly differentiated? The thought obviously suggests itself that the male being more complex, is more subject to faults of development.

**Syphilis** It is exceedingly difficult to get reliable statistics for the relative syphilis rate in male and female, but there is a very general belief among physicians that the disease works less havoc in women than in men. Hutchinson's so-called law, which postulated the possibility of a healthy mother bearing a syphilitic child, bore evidence to the many cases of symptom-free syphilis in women. This tenet of Hutchinson has, of course, been practically exploded since the introduction of the Wassermann test. There is also a strong clinical impression that women develop central nervous system syphilis (paresis, locomotor ataxia, etc.), much less often than men. Statistics from State hospitals show that males develop the CNS nervous disorders about four times as often as women, but there are many more original male cases than female. Nevertheless, statistics from 88 state hospitals show that the death rate for males with general paresis was 74.7 per cent, while that for females was 68.4 per cent. Dr. Pollock's figures indicate that the annual death rate from paresis is 341 per 100 males under treatment, and 279 per 1,000 females under treatment.

**Alcoholism** Alcoholism is about six times more frequent among males than among females. But it is remarkable that over 70 per cent of the cases of Korsakoff's syndrome, occur in females.

**Grave's Disease** This disease is six or eight times more common in females than in males, but it is the experience of most observers, as well as my own, that males who develop the severer forms display marked gynandromorphism with noticeable emphasis of feministic traits.

It is well recognized that among human beings there are many examples of incompletely differentiated individuals of each sex. The laity, as well as physicians, are familiar with persons of one sex whose voice, facial expression, postures and mannerisms suggest the opposite. Laurent,<sup>25</sup> Neugebauer,<sup>26</sup> Carpenter,<sup>27</sup> Buzzacott,<sup>28</sup> Wymore<sup>29</sup> and many others have written extensively on the subject of the sex inter-grade or bi-sexual man. Most of these authors, however, have discussed the question of either form—the purely morphological aspect—the degree

of view is an arch, that is, it is a curved structure made up of an indefinite number of segments, and capable of preserving its integrity though supported only at its extremities. The upper edge of the septum is not only one of these segments, but it performs the important function of the keystone of the arch. Consequently, if this is destroyed, as by an abscess of the septum, or if it is displaced either by accidental traumatism or during the performance of the submucous operation, the arch becomes re-established on a lower plane and a saddle-back deformity results. The fact that the nose is a tent-like structure of skin and soft tissues supported by this arch of bone and cartilage must be kept constantly in mind by the surgeon.

It may be difficult, if not impossible, to reconstruct a nose where some of the segments *have been destroyed*, without the transplantation of bone and cartilage. In recent injuries, however, without the loss of framework, the fractured and displaced fragments may be re-assembled in their normal position and held there until union occurs by means of the bridge-plant, which was devised by me a number of years ago and with which you are all familiar. I have found that

it is of great value in these fresh dislocations and fracture cases, but contrary to my early expectations, its use is limited in the case of old fractures with deformity, for here, owing to the elasticity of the skin and the contraction of the scar-tissue, the original deformity is apt to recur after removal of the bridge-splint. In nearly all of these old fracture cases, the bony framework is there, but it is displaced, causing deformity and interference with function. Here much can be accomplished by the intra-nasal, subcutaneous transposition of tissue, a method devised, perfected and used with such remarkable success by the late Dr. John O. Roe of Rochester, whose work in this field has never yet been equalled. We note with no little amusement that some of the recent aspirants to the field of plastic surgery have consigned to the "lumber-pile" intra-nasal methods of correcting nasal deformities, this is as it should be, for intra-nasal surgery especially in this field, demands a finer technique than is at the command of the novice in rhinology. Furthermore, the correction of nasal deformities requires in the operator a certain modicum of artistic talent, a God-given attribute, distributed, not to all who are called, but only to those who

Old Traumatic Deformity, Corrected by Subcutaneous Methods and by Transplantation of Bone

marked in the group of nephritis and hypertension. Thus, among other things, the females of the nephritis people have relatively longer abdomens, lower pelvis, lower sternum, lower set umbilicus and relatively greater length of long bones than the male. It is as though the external agents clashed with the predispositions of males of one species and females of another to produce nephritis. If one could express it in terms of experimental animals, it would be like saying that the nephritis group was composed of maleairedale terriers and female St Bernards.

### CONCLUSIONS

I. The greater disease and death rate of the male cannot be wholly ascribed, as Moebius insists, to greater exposure of the male to physical work, alcohol and venery. There is most suggestive evidence of a selective resistance and susceptibility directly related to the tissue quality differences of maleness and femaleness.

II. It would seem that in bi-sexual organisms sex may not only serve the second law of nature, but may contribute also the first law by providing special adjustments to environment for the good of each sex.

III. The lack of sex differentiation from the basic or common species type results in a lack of resistance for those diseases to which the species type is peculiarly susceptible.

IV. Males of one subspecies may be susceptible to a disease to which the female of another subspecies is susceptible, but to which the reciprocal female and male are resistant. (Maleairedale terrier—female, St. Bernard).

V. Members of a sex who develop diseases more common to the opposite sex show characters of incomplete differentiation toward their own sex.

VI. Sex appears to be a fundamental quality of the tissue protoplasm and the susceptibility to certain diseases behaves in many cases like a secondary sex character.

## CORRECTION OF NASAL DEFORMITIES\*

By WILLIAM WESLEY CARTER, A.M., M.D., F.A.C.S.

NEW YORK CITY

THE scientific correction of nasal deformities is based upon the developmental history of the organ and its histological structure. By scientific correction I mean the restoration of the nose to its normal status, from both a functional and cosmetic point of view by keeping in mind the laws of biology and using correct surgical methods. Permanent, satisfactory results can be secured in no other way and no reputable plastic surgeon should look upon his duties in any other light.

Aside from my own work on the Dynamics of Nasal Development and my reference to this

subject in some of my writings, I know of no surgeon who has paid any attention to the embryology and development of the nose in connection with the correction of deformities of this organ.

The external nose does not acquire its definite, individual form until after birth, and for sometime afterward marked changes occur, both intra- and extra-nasally. As a rule racial characteristics are delayed until after puberty, but the racial trend is often noted sometime before this epoch. In the white races the nasal bones are large and prominent, while in the yellow and dark races they are small and narrow, and are insignificant as segments of the nasal arch. The nose from both a mechanical and architectural point

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 13, 1925.

these should be superficial, so as not to compress the vacular layer of the flap. When the flap is finally sutured down and the first step of the operation is completed, before putting on the bandage, one should assure himself that there is an adequate supply of blood down to the tip of the flap. If this is pale and no blood flows from its distal end when it is gently massaged, we may be sure that necrosis will occur if it is left to itself. As originally suggested by me, I have, in such an emergency, applied a leech to the extremity of the flap and have seen the erstwhile pale and bloodless tissue assume a healthy, pink hue as soon as this worm began to work, once the flow of blood is started, the flap is safe as far as nourishment is concerned. In these cases heat, applied by means of my hot-water

nasal jacket is of great value when the circulation in the flap is endangered. The prompt application of heat is of great benefit in fresh injuries to the nose, both accidental and operative, not only is the swelling limited, but contused and even macerated tissue may be saved if the normal remarkable resistance of the nasal tissues to traumatism is further favored by the use of this agent.

The application of my methods in the correction of nasal deformities is best demonstrated by the figures thrown upon the screen, so I will conclude by saying that in no department of surgery are satisfactory results more dependent upon the recognition of correct principles and the use of the proper technique than in the surgery of this particular field.

## Deaths

BELKNAP, EUGENE W., Syracuse, College of Physicians and Surgeons of New York, 1892, Fellow American Medical Association, Member State Society, Obstetrician University and Free Dispensary. Died November 21, 1925.

CRARY, GEORGE WALDO, New York City, College of Physicians and Surgeons of New York, 1885, Fellow American Medical Association, Member State Society, New York Academy of Medicine, Alumni Association Bellevue and Roosevelt Hospitals, Consulting Dermatologist Roosevelt, Memorial and Nursery and Childs Hospitals. Died November 16, 1925.

DRURY, BENJAMIN FRANKLIN, Gouverneur, University of Vermont, 1859, Member State Society. Died October 22, 1925.

FULLER, EARL D., Utica, Albany Medical College, 1878, Fellow American Medical Association, Member State Society, Physician St. Luke's Hospital. Died October 27, 1925.

GARNSEY, WILLIAM SMITH, Gloversville, New York Homeopathic Medical College, 1880, Member State Society. Died November 15, 1925.

GOULD, RICHARD J., Buffalo, Buffalo Medical College, 1898, Member State Society, Surgeon Deaconess Hospital, Associate Physician Millard Fillmore Hospital. Died November 16, 1925.

HUMPHREY, RAY HOLLY, Endicott, Albany Medical College, 1913, Fellow American Medical Association, Member State Society. Died October 11, 1925.

JAGER, PHILIP, New York City, New York Eclectic Medical College, 1899, Member State Society. Died November 16, 1925.

JEWETT, CHARLES SHERMAN, Buffalo, College of Physicians and Surgeons of New York, 1890, Fellow American Medical Association, Member State Society, Visiting Physician County Hospital, Consulting Physician City Hospital. Died November 5, 1925.

PALMER, ALBERT H., Marlboro, New York University, 1876, Fellow American Medical Association, Member State Society. Died October 26, 1925.

PAUL, WILLIAM KENDALL, Belmont, Cleveland, Ohio, 1884, Member State Society. Died September 5, 1925.

ST. JOHN, FRANCIS W., Weedsport, Albany Medical College, 1887, Fellow American Medical Association, Member State Society. Died October, 1925.

STUDDIFORD, WILLIAM EMORY, New York City, Bellevue Medical College, 1891, Fellow American Medical Association, Fellow American College of Surgeons, American Gynecological Society, Academy of Medicine, Member State Society, Alumni Association Bellevue Hospital, Director Sloane Hospital, Consulting Gynecologist Presbyterian Hospital, Consulting Obstetrician Nursery and Childs Hospital. Died November 17, 1925.

WOOD, LOUIS CURTIS, Poughkeepsie, Bellevue Medical College, 1881, Fellow American Medical Association, Member State Society. Died September 21, 1925.

are chosen. One may doubt the accuracy of this statement when he looks over the long list of men who have recently taken up this work. The majority of nasal deformities resulting from disarrangement or destruction of some of the segments of the arch can be corrected by intra-nasal methods, and this always is the route chosen by those skilled in this field, for no noticeable scar results, and if the correct technique is used infection is far less apt to occur, especially is this true if bone and cartilage are being transplanted, as in saddle-back deformities. My original operation, devised in 1909, was through an incision between the eye-brows, but for the above reasons and others, I abandoned it many years ago in favor of the intra-nasal route. In my bone and cartilage work I always use the autogenous graft from the rib. I prefer this to the shin-bone because a section of the rib is easily removed and shaped to suit the deformity, moreover this bone is richly supplied with nutrient foramina and has not the ivory-like texture of the tibia. I preserve the periosteum on the outer surface and then split the rib, using the outer periosteum-covered half and include more or less of the cancellous tissue, depending upon the thickness desired. If it is necessary for the transplant to extend into the tip of the nose, I remove the graft, as I originally suggested several ago, at the junction of the rib and costal cartilage, the lower  $\frac{1}{3}$  of the transplant consisting of cartilage and the upper  $\frac{2}{3}$  of bone. This preserves the resiliency of the nasal tip. If the tip of the nose has a tendency to droop, I place a supporting bone strut in the lower edge of the septum. In my early work, I used on several occasions bone grafts without periosteum, these showed little vitality and were useful chiefly as a framework for the growth of bone from the adjacent periosteum-covered bone with which it was placed in contact. Periosteum-covered transplants have inherent power of growth and should generally be used in this work. Under no circumstances should paraffin or any other foreign body be introduced into the living tissues.

I am frequently asked how early in life should nasal deformity operations be attempted. I may say here that this question would not be asked so often if skilled attention had been given at once to the injuries of the nose so common during childhood, for these are responsible for most of the cases of nasal obstruction and deformity that demand surgical attention at a time of life when we would prefer to avoid operative interference, while the developmental forces of Nature are so active. But these cases are with us, and something must be done to relieve the nasal obstruction and to rectify the distorted framework, so that the action of these forces will be directed along normal lines. In my opinion this should be done as early as possible, otherwise the distortion assumes the importance of a congenital

deformity which is always more difficult to cope with as age advances. The nature of the surgical interference in children must be decided upon in each individual case, for the indications vary. No tissue should be sacrificed if we can possibly avoid it. This refers especially to the septum, which, as I have previously pointed out, exerts such an important influence in determining the shape of the adult nose. All of the distorted parts must be placed in a normal position and held there by a suitable splint until union occurs. If it is absolutely necessary to use a transplant, autogenous bone must be chosen, as this is a living tissue and capable of growth after transplantation. I have cases that show that normal development proceeds where periosteum-covered bone is implanted in contact with live bone in the young.

Where there is extensive destruction of the soft tissues of the nose, it is necessary to use flaps. I have found that the skin of the forehead, pedicled at the inner angle of the orbit, serves the purpose best. It may be necessary to introduce a transplant of bone, but this should be done subsequently. I have found that there is no special advantage in implanting the bone sometime before the flap is cut, this had best be done after the flap has become established in its new position and its vascular connections are secure. In cutting flaps I am using a method which I introduced several years ago. First, a paper pattern is made of the defective area to be covered, then a duplicate of this in adhesive plaster is made an ample margin for flap contraction being allowed. This is placed over the area to be included in the flap, the pedicle corresponding to the main source of blood supply. This pattern does not slip, its edge is easily followed by the knife and great accuracy in the shape and size of the flap is secured. The primary treatment of a skin flap is a very important matter and lack of attention to this has caused many a well-performed operation to result in failure. The following precautions should be closely observed. The pedicle should be as broad as possible and should include the chief blood supply. The flap should always include the subcutaneous tissues, as these contain the blood vessels. The flap should not be bent upon itself at too acute an angle, and there should be no compression of the blood vessels, either by a bandage or by making it into a tube, as has been advised by some. I believe that the making of a flap into a tube constricts the blood vessels, even though the base be cut broad, for I have seen some of these tube flaps lost. Furthermore, there is no need for this novel procedure, for not only are the raw surfaces of a flap amply protected by a thick coating of vaseline, but it has been conclusively demonstrated that the integrity of the blood-vessels is preserved by this agent. In suturing down the flap, as few stitches as possible should be made and

nity. Human nature varies but little whether it be in the wilds or the urban community. The problems of congestion, infection and epidemic will always arise when people gather together in large communities. These are less often a source of worry to a man whose territory is vast.

Secretaries throughout the union were all keen in enlisting common support on the part of the medical fraternity for the establishment of better health standards. Again human nature is much the same. We find men who feel it their civic duty to get their fellow physicians together to support educational work, to establish clinics and to fulfill their destiny as their brother's keeper. There is another large group who feel that in doing their daily dozen, looking after the sick in their immediate community and following the usual monotony of a busy doctor they are fulfilling as great a requirement. Each group can hardly survive without the assistance of the other. At every conference there is a type which is peculiar to each state. There is present the man who is keenly alive to the needs of the profession and who is willing to make the sacrifices of better organizing his work and to give his brother physician from other states the benefit of this experience. In time this man is a certain source of reference for the other states who have not yet met the same problems.

There was a delightful feeling of fellowship at the Chicago conference. It was interesting to note that many states have different types of machinery to accomplish the same results. There must be some good reason for this else the form of procedure would be more uniform. The same man was practically doing the same work even though called by some other name.

Periodic health examinations came in for careful consideration. The proper solution of this problem must take time but in gathering various sources of information in conference the American Medical Association is doing yeoman service. They are seriously anxious to correlate data to date.

Dr John Jennings of Kings wrote an excellent paper representing the work that Kings has thus far done. Dr Bryan of Maine reported that they had been busy with the problem now for many years. Pennsylvania has done considerable along this line. It is difficult to standardize the record of physical examinations so as to satisfy each individual. Lay organizations and insurance com-

panies who are anxious to secure all available statistics require a wealth of material which a busy practitioner can hardly take the time to get. Irrespective of what type of record is decided on a beginning has to be made somewhere. A careful physical examination will not require so much a super knowledge of medicine as a careful and painstaking thoroughness in the way in which it is done.

The conference brought out the fact that the Medical profession have a real obligation in making proper physical examinations and being ready to make these when the lay persons shall spread the gospel among the laity.

It is well worth recording that the Publicity Department of the American Medical Association is extremely cautious as to the way any news is given out from headquarters. Great care is shown that no one but authorized individuals shall talk with the press and nothing but facts be given. The result is that the report in Chicago, printed following the conference, gave an excellent description of what actually took place.

Dr W D Haggard, President of the American Medical Association stressed keenly his interest in periodic health work. The medical profession will have to be careful that the lay advertising does not get so far ahead of them that they are unable to meet the situation when it is properly launched. An important point which has been so frequently stressed in our own JOURNAL and by other organizations doing this work, has been the need for taking proper time for a complete examination, emphasizing the fact that an examination to be thoroughly made requires removing the clothing so that the patient may get an accurate and painstaking examination, and assuming nothing but that we examine our patient thoroughly and carefully and follow abnormalities to their ultimate conclusion.

It was also stressed that preventive health work was distinctly an examination of the apparently well and that too much attention should not be laid upon the fact that every person who was examined had a definite pathology already developed,—in other words, that we are examining healthy people and not sick ones.

We can assure our fellow practitioners in the State of New York that when the physicians of the United States are gathered together in conference they represent a healthy group of sturdy men whose ideals and earnest efforts to benefit mankind are an inspiration.

## THE ANNUAL SECRETARIAL CONFERENCE AT CHICAGO

The American Medical Association has shown rare foresight in gathering the secretaries from various states of the union at Chicago for the annual conference. This year the dates of November 21st and 22nd were assigned for this work. The editors of the various State Association Journals were likewise included in the program. It takes an occasion of this sort to bring out the vast differences which exist in the various states of the union. One goes with an idea that standardization is the ideal but one comes away convinced that the highest type of organization is the one which meets the local needs of the individual most satisfactorily.

When the licensure for the practice of medicine was in its infancy the various State Boards of Examiners established different standards in order to enable a physician to practice. It has been the

endeavor of the Federal authorities to bring these standards up to a definite point of common efficiency. As the plan has worked out we are glad to note that there are better doctors throughout the whole United States due not only to higher requirements and classification of Medical schools but also to the fact that the State Board of Examiners throughout the union are more nearly alike in their high requirements.

It was interesting to hear a physician from Wyoming state that in a number of counties in that state there was no resident physician. To be sure much of this county territory might have been covered by mountain and valley and more or less unoccupied but the fact remains that the type of medicine he would have to practice in so vast a district would not have quite the same significance as a physician practicing in a large commu-

ordinate with that of the commanders of artillery and engineers, and he is consulted in every maneuver made by the army

A physician is as important in civic life as in the army. He belongs on the local Board of Education. He is learned in science as well as in medicine, and can judge of what is practical and what is visionary in the curriculum. The sanitation of the school buildings and grounds, the medical examination of the pupils, the services of the school nurse, and the physical trainer,—these are a few of the medical matters in which a physician can render essential service to the school.

A physician belongs on the Board of Directors of his local bank. Health, both physical and mental, is a vital factor in a borrower's credit, and sanitation enters into the value of real estate collateral for a loan. Healthfulness is a vital asset in values of property with which banks have to deal. A bank needs the services of a physician quite as much as those of a lawyer.

The church opens a door of honorable service to the physician. The doctor and the minister of the Gospel both deal with things which money

and fame cannot secure, and both promote the qualities of courage, steadfastness, faith, and uprightness which make life endurable and worth living.

A physician also belongs in politics,—not for the sake of selfish officeholding and of salary grabbing, but because of its opportunity for public service. Especially are doctors needed in legislative halls. Their presence is also needed at hearings before local boards, especially on matters pertaining to health. Physicians generally are beginning to realize their duties in the political field, and are carrying their activities much further than merely passing resolutions.

Is it wise that a family doctor should be active in the school, the bank, the church and politics? Will his participation in these activities interfere with his medical practice and his standing among his medical colleagues and the people generally? For an answer consider the civic activities and connections of the leaders in the Medical Society of the State of New York, the District Branches and the county societies. The same characteristics which influence them to give their services to medical societies also impel them to be leaders in civic affairs.

---

## BUILDING THE HEALTH STRUCTURE

A great Health Structure is in process of making by three groups of builders,—the practising physicians, the official departments of health, and the lay organizations engaged in health and social service. The building has gone up irregularly as a group has added here a watch tower and there a work room, and elsewhere an exhibition hall.

The common foundations of all parts of the Structure were formed generations ago with the enduring stones of science which belong to all who will quarry them. The ground floors were built and occupied by physicians who sometimes complained of being disturbed by the construction that others were undertaking above them. The official departments of health builded turrets from which they could observe the fields to which the physicians claimed the exclusive right. And then lay organizations began to build walls connecting the towers, and to construct windows and hallways, and to put in telephones so that all the occupants could visit and talk together, and work and live as a harmonious whole.

The Health Structure is not complete, and in all probability it never will be. Old parts will continually be torn down and new constructed, the building will always resound with the din of hammering, the passageways will often be blocked with old rubbish and new cement, and there will ever be some confusion and incon-

venience. But the building is taking shape, and physicians are moving up from the lower floors and are occupying rooms in the towers and the upper courses of the walls, and they are finding the apartments pleasing and the outlook alluring.

Each of the three groups of workmen who are building the Health Structure has held annual meetings to draw up plans for the year's work, and the outer doors of the assembly rooms have sometimes been closely tiled. But a more brotherly spirit of cooperation is now prevailing. The discussions in the annual meeting of the Medical Society of the State of New York are largely on public health and preventive medicine. The annual conference of health officers is addressed by eminent clinicians on ways of dealing with preventable diseases of adult Americans who worship the god of personal independence, and only last week practicing physicians formed a goodly percentage of those attending the annual conference of lay health workers under the leadership of the State Charities Aid Association and the Trustees of the Milbank Fund.

The outlines of the builded parts of the Health Structure already stand out clear and beautiful, and with them as a basis, the several groups of workmen are eagerly striving to execute the plans drawn on a common trestle board through the united wisdom of their grandmasters.

## LEGISLATORS AND PETITIONS

During the coming session of the Legislators the law makers will be deluged with petitions for and against proposed laws. The legislators are fully aware how the signatures are obtained and how slightly many of the signers are interested in the contents of the petition. Nevertheless the petitions have far more influence than may at first be suspected,—and here is how it comes about.

Every legislator reads his mail to at least the extent of finding out what his letters are about. He also looks carefully at the signatures to see that he does not overlook anybody of prominence.

The legislator looks at petitions in the same way. He glances at their contents and then scans carefully the names of the signers. If he finds the names of a few prominent persons whom he knows, he gives careful heed to their wishes. He knows that prominent business men, office holders, and even judges on the bench are prone to sign petitions without giving due thought to what they do, and yet he does not ignore their written desires.

Many legislators are swayed by the signatures of prominent persons who have no real interest in that for which they ask, but the legislator takes no chances. He remembers that the person of power has asked him to do something, and he is influenced by the request. The more conscientious a legislator is, the more likely is he to give heed to the petitions.

In one County the opponents of the Practice of Medicine Act got up a petition asking their legislative representative to support the legalization of a cult whose practitioners had almost no educational qualifications. The legislator found on it the names of a surrogate and a prominent bank president, and he said, "These men signed the petition, and there must be some virtue in what they seek."

The fact was that a prominent politician whose son-in-law was a practitioner of the cult, said to each signer, "Many unqualified persons are posing as healers, and this petition asks that all who practice the system shall be licensed in order to keep out the incompetent,"—and Mr. Prominent Person signed on the dotted line.

What can doctors do to counteract these petitions? Obviously, they too should get out petitions and have them signed by prominent persons, also get prominent persons to write personal letters to their legislators asking that all who practice the healing art should possess a single standard of educational qualification.

It is reasonable to expect that the physicians of New York State could each secure an average of one letter from a prominent person. That would make 1,600 letters or 80 to each legislator, and those would be no ordinary letters such as the legislators throw in the waste basket, they would be personal letters from prominent people whose opinions the legislators respect.

## THE PHYSICIAN IN CIVIC AFFAIRS

Dr. A. H. Palmer, of Marlboro, Ulster County, whose funeral was held on October 22nd, was held in high esteem by his fellow townsmen because he was "active in almost every important community movement," according to an appreciation of his life printed in the Marlboro Record. He was a leader in medical societies, a member of the Board of the Methodist Church, Vice-President of the Marlboro Bank, and "one of Marlboro's most beloved and loyal citizens." He was much more than a physician treating individuals. He gave his services to his community along those civic lines for which his training as a physician had fitted him.

The evolution of medicine has developed the principle of a physician's civic responsibility. Many conditions which a doctor treats are the result of social conditions,—of factory life, poor housing, polluted water supply, or uncontrolled cases of contagious disease. Shall a doctor say, "these conditions are beyond my control, and I will have nothing to do with them, but will stick strictly to my own business of treating the sick

who call me?" The time has gone by when a doctor can say that conscientiously. The people look to him for advice and leadership in educating the people regarding the dangers of such conditions as dirty milk, and arousing them to institute an efficient system of milk inspection.

Modern health and efficiency require that physicians shall take their proper place of leadership in all phases of civic affairs. It is theirs to lead in all health matters of a community, just as it is the duty of the minister of the Gospel to take the lead in morals, and of the civil engineer to lead in matters pertaining to good roads and bridges.

A physician has his place in every phase of civic life of a community. His position today is like that of a medical officer in the Army. A generation ago a physician was merely tolerated in the army, and he had no rank or authority. He had achieved rank with little authority at the outbreak of the World War. He emerged from the World War with both rank and authority, and now has an honored place on every staff co-

ordinate with that of the commanders of artillery and engineers, and he is consulted in every maneuver made by the army

A physician is as important in civic life as in the army. He belongs on the local Board of Education. He is learned in science as well as in medicine, and can judge of what is practical and what is visionary in the curriculum. The sanitation of the school buildings and grounds, the medical examination of the pupils, the services of the school nurse, and the physical trainer,—these are a few of the medical matters in which a physician can render essential service to the school.

A physician belongs on the Board of Directors of his local bank. Health, both physical and mental, is a vital factor in a borrower's credit, and sanitation enters into the value of real estate collateral for a loan. Healthfulness is a vital asset in values of property with which banks have to deal. A bank needs the services of a physician quite as much as those of a lawyer.

The church opens a door of honorable service to the physician. The doctor and the minister of the Gospel both deal with things which money

and fame cannot secure, and both promote the qualities of courage, steadfastness, faith, and uprightness which make life endurable and worth living.

A physician also belongs in politics,—not for the sake of selfish officeholding and of salary grabbing, but because of its opportunity for public service. Especially are doctors needed in legislative halls. Their presence is also needed at hearings before local boards, especially on matters pertaining to health. Physicians generally are beginning to realize their duties in the political field, and are carrying their activities much further than merely passing resolutions.

Is it wise that a family doctor should be active in the school, the bank, the church and politics? Will his participation in these activities interfere with his medical practice and his standing among his medical colleagues and the people generally? For an answer consider the civic activities and connections of the leaders in the Medical Society of the State of New York, the District Branches and the county societies. The same characteristics which influence them to give their services to medical societies also impel them to be leaders in civic affairs.

---

## BUILDING THE HEALTH STRUCTURE

A great Health Structure is in process of making by three groups of builders,—the practising physicians, the official departments of health, and the lay organizations engaged in health and social service. The building has gone up irregularly as a group has added here a watch tower and there a work room, and elsewhere an exhibition hall.

The common foundations of all parts of the Structure were formed generations ago with the enduring stones of science which belong to all who will quarry them. The ground floors were built and occupied by physicians who sometimes complained of being disturbed by the construction that others were undertaking above them. The official departments of health builded turrets from which they could observe the fields to which the physicians claimed the exclusive right. And then lay organizations began to build walls connecting the towers, and to construct windows and hallways, and to put in telephones so that all the occupants could visit and talk together, and work and live as a harmonious whole.

The Health Structure is not complete, and in all probability it never will be. Old parts will continually be torn down and new constructed, the building will always resound with the din of hammering, the passageways will often be blocked with old rubbish and new cement, and there will ever be some confusion and incon-

venience. But the building is taking shape, and physicians are moving up from the lower floors and are occupying rooms in the towers and the upper courses of the walls and they are finding the apartments pleasing and the outlook alluring.

Each of the three groups of workmen who are building the Health Structure has held annual meetings to draw up plans for the year's work, and the outer doors of the assembly rooms have sometimes been closely tiled. But a more brotherly spirit of cooperation is now prevailing. The discussions in the annual meeting of the Medical Society of the State of New York are largely on public health and preventive medicine. The annual conference of health officers is addressed by eminent clinicians on ways of dealing with preventable diseases of adult Americans who worship the god of personal independence, and only last week practicing physicians formed a goodly percentage of those attending the annual conference of lay health workers under the leadership of the State Charities Aid Association and the Trustees of the Milbank Fund.

The outlines of the builded parts of the Health Structure already stand out clear and beautiful, and with them as a basis, the several groups of workmen are eagerly striving to execute the plans drawn on a common trestle board through the united wisdom of their grandmasters.

# MEDICAL PROGRESS

**Human Intestinal Parasites as a Cancer Inciting Factor**—Willy Meyer (*American Journal of the Medical Sciences*, October, 1925, clxx, 4), as a result of an intensive study of the literature of cancer, emphasizes the utter improbability of the existence of a specific causative cancer micro-organism. Continued study of the literature has deepened that conviction, but has not discouraged the author from trying to gain an insight into the genesis of the disease. He discusses the relation of ova, larvae and worms to cancer incitement, having selected them for special consideration, not so much because of the interest attaching to them *per se*, but rather as representatives of all the multifarious factors known to have set in motion, in one instance or another, a train of events which terminated in the cancerous tumor. Summarizing his survey of the question with reference to ova, he says that precancerous lesions, that is to say, nonhealing superficial ulcerations, are produced by the spiked ova of the *Bilharzia* parasites in the bladder, the bowels, the rectum, and the genital tract. But even ova having a smooth surface may become contributory factors in the production of precancerous lesions, as, for example, when liver flukes and ascaris worms deposit ova in the gall-bladder, in the bile ducts, or in the ducts of the pancreas. The lesions due to the migration of larvae in the system, the author says, appear neither sufficiently severe nor sufficiently lasting to produce a precancerous condition, although, when there are frequently repeated massive larval invasions through the skin, as in the case of the hookworm or of schistosoma, or in cases of massive auto-infection (tapeworm), the migration of the larvae may cause lesions having cancerous potentialities. In contradistinction to migrating larvae, encapsulated larvae are commonly found capable of becoming the inciting factors of precancerous conditions. It is possible that the toxins emanating from encapsulated larvae may likewise be cancer-inciting factors. Dead adult liver flukes, enclosed with their ova and with cellular detritus in nodules of the biliary system or in the pancreas, also adult ascaris worms that have invaded the ducts of these organs, may possibly by the combination of mechanical pressure, foreign body irritation, and toxins produce therein a precancerous state. But cancer-inciting factors, while capable of initiating a so-called precancerous state, evidently do not govern the behavior of the tissue during this state, for the appearances in the tissue arousing suspicion may be aggravated, may become stationary, or may recede after the initiatory irritation has ceased to exist.

**The Results of Operative Treatment of Malignant Disease of the Breast.**—H P Winsbury White (*Practitioner*, October, 1925, cxv, 4) has followed up patients operated upon between 1900 and 1913, and has succeeded in obtaining the desired information in 92 cases. In studying the cases in which death occurred within three years of the operation for signs making a bad prognosis a certainty, one or other of the following signs was found in every instance: (1) Fixation of the growth to the pectoral fascia or muscle, (2) fixation of the growth to the overlying skin, (3) palpable axillary glands, (4) microscopical evidence of growth in the axillary glands. A study of the patients who survived for more than ten years showed that, with one exception, the same rule held good. There is no doubt that fixation of the growth to the deeper structures is a physical sign which almost assures a bad prognosis in cases which may otherwise be considered operable. The microscopical demonstration of the carcinoma in the glands does not render the outlook anything like so grave as might at times be supposed. With regard to fixation of the growth to the skin, and the mere palpable enlargement of the glands, many of the long survival cases had both of these signs present, so that in the absence of the unfavorable indications previously mentioned, these must not be looked upon as making the outlook more serious, unless clinically there are manifestations that the glands are undoubtedly carcinomatous. The author concludes that in operable cases, while recognizing certain features as making a bad prognosis a matter of certainty in some cases, and as highly probable in others, the outlook is always a matter of conjecture, in spite of the most radical operations.

**The Toxic Effects of Lead**—W Blair Bell, W R Williams and L Cunningham (*Lancet*, Oct 17, 1925, ccx, 5329) have observed the toxic effects in the human subject of measured quantities of lead administered intravenously at known intervals, some 200 patients in all having received injections. The lead was given to inhibit the growth of cancer cells, in carrying out Bell's method of the non-operative treatment of malignant growths, hence the accuracy of these observations which makes them important in any consideration of lead poisoning. The changes in the red blood cells consist in a punctate basophilia which may appear within a few hours of the initial dose, anemia with its accompanying polychromasia, anisocytosis and poikilocytosis occur later, and may be only temporary or, if bone marrow be involved, may persist. Leucocytosis has frequently been observed, especially shortly

after an intravenous administration of lead, leucopenia occurs occasionally, but neither of these phenomena appears to be constant. A slight relative lymphocytosis may occur, but this is not generally marked. There is a definite increase in the number of granular forms of leucocytes. Anemia is a consequence of the long-continued administration of lead, and is accompanied by the usual symptoms of that condition—headache, lassitude and palpitation. The blue line at the gum is rarely seen when lead is administered intravenously. Nausea and vomiting appear to be dependent upon the amount of lead administered, but occur after a smaller total quantity, when given in massive doses, than after a larger total amount given by long-continued administration of small doses. Intestinal colic occurs with considerable frequency after the administration of massive doses, it is not seen after the long-continued administration of a smaller quantity of lead. Psychopathies may occur after the intravenous administration of lead, but they are rare. The retina may be affected, when this occurs it is probable that it is a concomitant of renal involvement. The toxic effect of lead on the kidneys is sufficiently frequent and of such magnitude as to require the greatest caution in the administration of this drug. In general it is found that the functional impairment caused by many small doses is less in degree, but more permanent than that caused by occasional large doses. The earliest indications of renal failure are diminution in the quantity of urine secreted and the occurrence of albuminuria and edema. A rise in the blood-urea does not occur, as a rule, until the damage is sufficiently great to be detected clinically. As in nephropathies due to other causes, it is difficult to correlate functional impairment with pathological change. Pathological changes in the liver are not so marked as in the kidney, and the main impairment of function seems to be connected with the bile-producing mechanism. In view of these many untoward consequences of the administration of lead, it is obvious that the use of this poison in the treatment of cancer is a method that should never be attempted by those who have not complete laboratory facilities at their disposal, and who have not studied for some time the actual treatment of patients at the hands of experts. The author has since published the details of his cancer treatment. This will be reviewed in this department when available.

**The Origin and Significance of Postural (Orthostatic) Albuminuria.**—James W. Russell (*Lancet*, October 23, 1925, ccix, 5327) points out two sources of fallacy which often interfere with the recognition of cases that are strictly orthostatic in nature. It is usually held that the urine passed immediately on getting out of bed by a patient suffering from orthostatic

albuminuria is invariably free from albumin. But this statement is incorrect of many genuine cases. The albumin excretion set going by the upright position continues, and sometimes increases for half an hour or more after the return to bed. A second source of fallacy lies in the fact that during diuresis the upright position loses its effect on the excretion of albumin, for this reason it is never safe to depend upon the absence of albumin from a single plentiful specimen of urine. From a study of a series of scarlet fever patients Russell concludes that many patients suffering from scarlet fever, who present no albuminuria during the period of rest, develop an orthostatic albuminuria immediately after getting up. Some of these albuminurias persist for a considerable time or even permanently. Some cases of recognized scarlatinal nephritis are ultimately represented by an albuminuria of the orthostatic type. Orthostatic albuminuria may follow other forms of specific infection, or even, though rarely, arise as an end-result of a mild acute nephritis of the ordinary type. The proportions of serum globulin and serum albumin are not constant in cases of either orthostatic or nephritic albuminuria, and do not enable a differential diagnosis to be made. It is suggested that in many cases the orthostatic reaction is the result of slight renal damage, though it may occur from mechanical causes. Some response to posture occurs in most cases of nephritis, and possibly in all forms of albuminuria.

**The Nature of the Eclampsogenic Protein.**—Alexander Hynd presents in the *Lancet*, October 31, 1925, ii, 5331, a contribution to this vexed question, his findings being based on a study of the urinary proteins in 26 cases, 12 of which were diagnosed by the clinician in charge as albuminuria of pregnancy, while 14 were described as of the eclamptic type. In the 12 cases of "albuminuria of pregnancy" without convulsions the specific rotation of the urinary albumin averaged  $-55.81^\circ$ , and thus agreed for that found for human serum albumin under similar treatment, namely  $-54.47^\circ$ . A similar close agreement in specific rotation, namely  $-54.27^\circ$ , was found in five cases of proteinuria not associated with pregnancy. On the other hand the 14 cases of eclampsia were sharply divided into two groups, one group having an average specific rotation of  $-56.37^\circ$ , and the other group of eight having an average of  $-38.5^\circ$ . The optical activity of the former group agrees well with that of serum albumin ( $-54.47^\circ$ ), while that in the latter approximates closely to that of cow's lactalbumin ( $-47.17^\circ$ ). Accordingly it is suggested (a) that in certain types of eclampsia the urinary albumin may be mainly lactalbumin, (b) that eclampsia may be an anaphylactic reaction due to the circulation in the blood of this foreign protein, and

(c) that the mammary gland may be an important factor in the causation of eclampsia. It may be, for example, that normally small amounts of lactalbumin may find their way into the blood stream during pregnancy, the usual result being the establishment of an immunity to this protein. When, however, this immunity is slight and a sudden discharge, from any cause, of a large amount of lactalbumin occurs and breaks through the immunity, eclampsia is very likely to result.

**Influence of Hypnotism on the Renal Function**—Heilig and Hoff give the results of some experiments conducted in the psychiatric clinic of Wagner-Jauregg, Vienna. The same authors had already reported the ability to influence by hypnosis the composition of the gastric juice, the motility of the stomach and the progress of chymification. In the present research similar efforts were made to alter the secretion and composition of the urine. The subjects were placed in the hypnotic state in the recumbent position. They comprised chiefly healthy female attendants and were, of course, willing volunteers. They were given only the ingesta commonly employed in renal testing—chiefly weak tea in definite amounts. The method consisted in suggesting to them in a variety of ways that they were well, happy, etc., on the one hand, and ill and miserable on the other. Under the former suggestion they were shown to retain water, to gain weight, to retain chlorides and phosphates, etc. Under the unpleasant suggestions the reverse was seen—diuresis, waste of chlorides and phosphates and lost weight. The fluctuations in weight were of course slight, varying with the behavior of the water. There is no evidence adduced to show that the metabolism was affected, all of the fluctuations being explained by the behavior of the renal secretion.—*Deutscher med Wochenschrift*, September 25, 1925, 11, 39.

**Double Action of Insulin.**—Muller and Wiener continue their work on the intracutaneous action of insulin. In addition to the action of the hormone when thrown directly into the veins it has been learned that still more remarkable and quite separate power of destroying sugar is exerted through the vegetative nervous system, when a little insulin is injected parenchymatously into any organ well supplied with the latter. When injected directly into the circulation insulin simply destroys the excess of sugar already formed, and has incidentally a theoretic disadvantage, for if it overacts against the sugar the body reacts by producing more sugar. But exhibited intracutaneously the action of the hormone is exerted on the glycogenic function of the liver, and the result is that the dextrose is changed to glycogen, so that sugar disappears from the blood as in the first case. In this second form of action the dose used seems im-

material, a minute quantity sufficing. When the substance is injected entirely into the veins this action is not exerted at all, and in the intracutaneous exhibition there is no glycolysis in the blood. But when subcutaneous injection is practiced both actions are present, although the glycogenic function is less in evidence than glycolysis. The authors draw no conclusions which bear on practice. Intracutaneous injection would seem to mean an economy of dose, while the preventive scope of the action seems superior in theory to the mere glycolytic property of insulin in the circulation. The subcutaneous route is seen to combine both actions although in a very different degree. It is of interest to note that some of the laboratory work is being carried out at Columbia University, New York.—*Münchener med Wochenschrift*, Oct 2, 1925.

**Insulin in Uremia and Cholesterinemia**—Flandin points out that the power of insulin to reduce blood dextrose may be applicable to other blood ingredients when present in excess. Indeed, animal experiment has shown that insulin can reduce the amount of substances believed to be pathogenic in excess, as urea and cholesterin. The author selected a case of chronic nephritis with albuminuric retinitis in which there was a blood urea content of 2.20, which could not be lowered by strict diet. He injected insulin and found that after from 15 to 30 injections it was possible to reduce the urea to 1.20 with corresponding clinical improvement. He kept this patient down to this level for six months, at which time his service ended. His successor stopped the insulin treatment, apparently as a crucial test of its value, and the patient rapidly became worse and in three weeks was dead.

In regard to cholesterinemia Professor Chauffard has recently shown that albuminuric retinitis cannot develop unless there is an excess of blood cholesterin. Whatever the value of insulin in uremia it seems to have a field in this form of retinitis. Chauffard appears to have caused the disappearance of the lesion in at least one case, and in Flandin's case.—*Le Bulletin Médical*, September 2-5, 1925, 11, 36.

**Glucose Infusions and Insulin in the Preparation of Poor Surgical Risks**—David Fisher and Edmund H. Mensing (*Boston Medical and Surgical Journal*, October 15, 1925, 16) state that recent developments of the use of glucose infusions and insulin in preoperative acidosis, in shock, and in starvation, have given the internist and surgeon an effective method whereby a poor or apparently hopeless risk can, in a comparatively short time, be transformed into a good or fair risk. In the authors' hands this method has proved effective in 18 cases of shock. A sterile solution of C. P. glucose is used in 10 to 15 per cent strength,

500 to 1,000 cc being given. For every two grams of glucose injected one unit of U20 insulin is administered. The total amount of insulin to be given having been estimated, one-half of this amount is injected subcutaneously when one-third of the total glucose solution has entered the veins, and the remainder of the insulin is given after the administration of the glucose has been completed. The entire time occupied by the administration of the glucose should be at least 90 minutes. Glucose and insulin are indicated not only in the type of cases above mentioned, but also in patients whose preoperative condition is good, but who are to undergo a serious operation, in which some difficulty is anticipated.

**Pseudoparesis Due to Fat Embolism**—Von Sarbo of Budapest relates a case which is probably unique. On the day following a severe compound fracture in a middle-aged man, for which amputation was eventually required, a cerebral crisis developed during which the patient remained unconscious for six days and awakened with an acute psychosis. The surgeon made the diagnosis of fat embolism of the brain. The symptoms which developed suggested a diagnosis of either progressive paralysis or traumatic psychosis, and the consulting neurologist ruled out the early diagnosis of fat embolism. Another neurologist made a diagnosis of typical progressive paralysis, and the author, called in at the same time, at first concurred in this opinion. But the Wassermann blood and spinal fluid tests proved negative throughout and the author returned to the original diagnosis—multiple fat embolism. The psychosis gradually cleared up and the patient is now engaged in his regular business. Study of the literature of cerebral fat embolism does not appear to show a parallel case, and the entire literature of the subject is meagre. *Klinische Wochenschrift*, October 1, 1925, iv, 40.

**Nature of Death after Fat Embolism**—Paul and Windholz read a paper on this subject before the Pathological Society of Vienna (*Wiener klinische Wochenschrift*, Oct 1, 1925), in which they gave an autopsy report of a woman who died of uremic coma following a compound fracture. A typical uremic ulcer was found in the ileum. Nevertheless, there were no evidences of chronic nephritis as such. The kidneys, as well as numerous other structures, were the seat of multiple fat embolism and the number of emboli was greater here than elsewhere—sufficient evidently to inhibit the renal functions. The authors now injected marrow fat repeatedly in rabbits and found invariably a retention in the blood of nitrogen sufficient to conform with that present in fatal human uremia. In addition there was a disappearance of blood sugar similar to that produced by insulin and due to interference with the glycogenic function of the liver. It is known, however, that

many animals can tolerate injections of bone marrow, and we know little of the nature of this immunity, but it is evident that the cerebral symptoms of fat embolism are not due entirely to local embolism. Other factors can contribute and the fat itself may, through its catabolic products, set up an auto-intoxication.

**Clinical Value of Some Recent Tests for Liver Function**—Howard F. Shattuck, John C. Brown and Marjorie Preston (*American Journal of the Medical Sciences*, October, 1925, clxx, 4) have made a comparative study of some of the newer and more promising tests for liver function, in a clinical material comprising 173 patients. The Fouchet test proved unreliable in their hands for detecting minor grades of bilirubinemia. In other respects the van den Bergh test served very well in its place. The van den Bergh test was found to have distinct value in the study of liver function and jaundice. Positive results with both reactions indicate impaired liver function, but the extent must be determined by the icterus index or dye test. It helps as a specific qualitative test for bile pigment to control readings of the icterus index in the zone of latent jaundice. It distinguishes between hemolytic and obstructive jaundice. The study seemed to indicate that the icterus index is the most useful single functional liver test for clinical work. It is easily and quickly performed, unobjectionable to the patient and free from danger. Its greatest value is in the diagnosis of cases of cholecystitis and cholelithiasis without clinical jaundice. It is a distinct aid in distinguishing between obstructive jaundice due to malignancy and catarrhal jaundice by showing whether the jaundice is increasing, diminishing, or stationary. It is helpful in the diagnosis of cirrhosis and malignant metastases in the liver, though apparently less so than the dye retention test. It may indicate the degree of cardiac decompensation. It serves as a guide to toleration by the liver of arsenicals in the treatment of syphilis. It will determine whether obstructive jaundice has been relieved by operation and it will aid in the differentiation of the primary and secondary anemias. The Rowntree-Rosenthal dye test is of supplementary value in measuring liver function. For clinical work it is more complicated, more objectionable to the patient and may not be entirely free from danger. It seems, however, to be of greater value than the icterus index in the diagnosis of cirrhosis and malignant metastases in the liver. In surgical cases with jaundice, the dye test helps to determine the degree of damage to the liver parenchyma, and hence the surgical risk. Its greatest value apparently is in the diagnosis of liver disease in patients without jaundice. Here a positive result points to liver involvement, a negative result helps to rule it out.

By GEORGE W. WHITESIDE, Esq.  
Counsel, Medical Society of the State of New York

## FRACTURE OF THE HUMERUS—VOLKMANN'S PARALYSIS

On the 22nd of February a boy about four years of age, while playing on the street, fell and sustained an injury to his arm and hand. On the following day the defendant physician was called to render service to the boy. In an action of malpractice against this physician it was charged that he was negligent and careless in his treatment and care of the boy, in that he had failed properly to set the fracture of the boy's arm and had improperly bandaged the same, that he failed to apply the necessary attention or administer the necessary medicines and appliances to bring about a good result, and that by reason of the defendant's alleged carelessness the hand and fingers of the patient became paralyzed and diseased, the hand becoming absolutely useless and the general health of the boy being impaired. It was also claimed that the boy had permanently lost the use of the injured hand and arm, and damages were sought for these injuries. An action was also instituted by the father to recover for medical expenses and loss of his son's services.

It appears that on February 22nd, at the time of the fracture to the boy's right elbow, he was treated by a physician who had X-rays taken. The defendant was called in on the evening of the following day, at which time he was told that another physician had, at the time of the injury, put the arm up in a temporary splint. Upon examination on February 23rd, the defendant found the arm in full extension, with marked swelling at the elbow. He removed the cotton bandages and wooden splint that had been previously put on by the other physician. The splint that was then on the arm was an anterior-posterior splint extending from the wrist to the shoulder. The defendant then slightly manipulated the arm to determine the extent of the fracture and flexed it to an angle of about 15 to 20 degrees. Because of the swollen condition he ceased further manipulation of the arm. At that time he placed the arm in slight flexion and reinforced it with a temporary splint and bandage. He also advised the parents that it was a very bad fracture, as it was at the elbow joint, and that it might not be possible to reduce it without an anaesthesia and that X-rays must be taken.

On the following morning, February 24th, at the office of a roentgenologist, the defendant met the patient and his parents, where X-rays were taken. The X-rays showed a marked separation

of the fragments at the site of fracture. The defendant then reduced the fracture in the office of the roentgenologist and had an X-ray taken after the reduction. This X-ray showed the fragments in good position.

Because of the swelling and the failure of reduction for a period of forty-eight hours, it was necessary for the defendant to use pressure to hold the arm in marked flexion. He applied a metal splint held in place by strips of adhesive plaster. On the same evening he called at the patient's home to determine the amount of pressure, so that the circulation would not be interfered with. There was no swelling of the fingers at this time and the color of the hand and arm was good and there was no complaint from either the patient or his parents. Instructions were then given to the parents to watch the arm and if there was any increase in the swelling immediately to notify the defendant. He further told them to call upon him in four or five days, at which time he would have further X-rays taken.

On February 28th he again met the patient, with his father, at the office of the roentgenologist, removed the bandage and metal splint and had further X-rays taken at that time, which showed the bones in good apposition. The metal splint was re-applied and the arm redressed, being kept in its former position.

The seriousness of that type of fracture and the danger of complications, such as the impairment of the hand and ankylosis of the joint, were explained to the parent. The defendant likewise advised the parents of the necessity for early manipulation and passive and active motion of the injured member.

On March 3rd the boy, accompanied by his father, called at defendant's office. Upon examination there was found a slight erosion of tissue at the point of the elbow and also at the wrist, due to excessive odema and the pressure of the adhesive plaster on the arm. He advised the father to bring the boy to his office daily, but both the parents being engaged in business they didn't find it possible to do so, and therefore, the patient was brought to the defendant at intervals of every two or three days until the end of March. The physician repeatedly endeavored to impress upon the parents the necessity for daily treatment of the injured arm, and also gave the father instructions to be carried

out at home in the manipulation of the hand and arm. Toward the end of March the boy developed a Volkmann's paralysis due to the non-manipulation of the arm and, in the defendant's opinion, due to the excessive edema which had taken place in the first forty-eight hours. At this time he advised the father to consult a specialist. At the first appearance of the Volkmann's paralysis the defendant tried to extend the fingers by bandaging them with splints. The parents failed to consult a specialist until about ten days after the defendant had advised them to do so. The specialist who was consulted advised the parents that the boy was developing a Volkmann's contraction of the fingers, and prescribed manipulation, massage, hot and cold bathing and keeping the fingers extended on splints, and that the massage be done by a proper masseur, and furnished the name of a masseuse to the parents. However, the parents failed to procure the services of this masseuse until several weeks later, and then had her massage the boy's arm every five or six days instead of daily. The masseuse likewise was compelled to discontinue her services to the boy, as the parents refused to follow the advice of daily massage. The mother, on one occasion, when giving the arm a hot water bath as prescribed, had the water too hot and because of the lowered sensitiveness of the arm, caused the arm to be burned. The child was not seen by the defendant after April 19th.

Another specialist was consulted by the parents, who had an X-ray taken of the arm. To him the picture indicated that a nerve controlling the motion of the wrist and hand was being

pressed on by the ends of the bone at the point of fracture, which might have produced the Volkmann's paralysis. This specialist, when asked by the parents, refused to recommend an operation and referred them to a nerve specialist and recommended that an examination be made before operating. This specialist recognized, from his examination, that the fracture was a difficult one to reduce.

The child was thereafter taken to a clinic, where he was receiving baking and massage treatment about three times a week. A physical examination of the child made on July 22nd showed that he was an anemic, undernourished boy about four years of age, that the right elbow showed moderate swelling at the joint, irregularity and thickening of lower end of humerus, the joint action slightly restricted, flexion limited to 90 degrees, extension to about 125 degrees, supination limited to 50 per cent, pronation greatly restricted, on the anterior surface there was an irregular, thick scar about  $1\frac{1}{4}$  inches by  $\frac{1}{2}$  inch. The examination further disclosed atrophy of the muscles of the forearm, with diminished sensation. There was likewise atrophy and diminished sensation of the right wrist, hand and fingers. The wrist was stiff, the fingers at the time were extended on a Jones splint, no contractures being present, and there being slight movement of the fingers.

When these actions came on for trial they were on the calendar for several days, and not being answered on behalf of the plaintiffs, the court dismissed the complaints, terminating the same in favor of the defendant.

---

### BURN FROM HOT SAND BAG IN OPERATION

A physician, upon examination of a seven-year-old boy, found a condition of mastoiditis warranting surgical interference and advised an immediate operation. Arrangements were made and the boy was removed to a hospital where, in the early afternoon, the physician prepared to operate upon him. Upon his arrival at the operating-room he found the boy on the operating-table fully prepared for the operation, both the boy and table being draped with sterile dressings and the necessary props. The mastoidectomy was performed without any untoward results.

Upon the day following the operation the mother of the boy called the surgeon's attention to a slightly reddened area upon the child's back at a point between the shoulders. At this time the reddened area was about the size of a twenty-five cent piece. This condition became progressively worse, the area suppurated, and there was a sloughing of the tissues. It took several months

of treatment by the surgeon and another physician before the abrasion had completely healed.

A suit was instituted against the surgeon and the hospital charging them with negligence in the preparation of the child for the operation, and specifically charging that in placing the child upon the operating-table sandbags, which were either hot or saturated with iodine, were used, thereby causing the burn to the patient's back.

The action finally came on for trial and after the introduction of the plaintiff's testimony the complaint was dismissed as to both the physician and the hospital.

If the surgeon in this instance were held liable for the result complained of, then in no case could a surgeon rely upon the nurses and various hospital assistants in the preparation of a patient for operation without subjecting himself to possible personal liability.

# OUR NEIGHBORS

## MEDICAL SOCIETY OF NEW JERSEY

The Medical Society of New Jersey held its 159th Annual meeting June 18th to 20th, 1925, in Atlantic City, and the official transactions have just come to us in the form of a supplement to the September issue of the Journal of the Medical Society of New Jersey. We were interested in looking up information concerning the organization of the Medical Society of our sister State.

The Society has 2,227 members, while 1,340 doctors listed in the State are not members. The annual dues are \$10, but the Society receives about \$27,000 as its total income from all sources, including advertisements in its Journal.

The organization of the Medical Society of New Jersey is much like that of New York State. There are 21 county medical societies, and 5 councilor districts. A board of trustees manages the finances of the Society. One of the principal committees is that on Welfare, which manages the legislative activities of the Society. Last year it sponsored a bill restricting the use of the title "doctor" to those who have the necessary educational qualifications. The report says: "The bill failed despite every effort on the part of our Society, and of many influential citizens whose only object was the protection of the public in health matters by guaranteeing to the people that the title 'doctor' meant that the person using it was qualified by special training to treat the sick. Your Welfare Committee has decided by a majority vote to recommend that the 'Doctor Title' bill be reintroduced at the next session of the Legislature. It is the duty of every member of the Society to get behind this measure. We shall succeed or fail in proportion to the aid received from the individual members of the Society."

The Society employs an Executive Secretary at a salary of \$10,000 annually, but it allocates this salary under three items corresponding to the Secretary's triple duties:

1 Secretary of Welfare Committee	\$2,000
2 Publicity Executive	5,500
3 Editor of State Journal	2,500
	<hr/>
	\$10,000

The Welfare Committee demands intensive work of the Executive Secretary during the time of the legislative session.

As Publicity Executive, the Executive Secretary promotes medical education among the people. He devotes considerable space in his annual report to a discussion of methods of newspaper publicity, and points out a difference

of opinion between newspaper editors and the doctors regarding what is news. He also refers to the news value of a challenge issued by a Newark cultist to the United States Public Health Service to submit to a test to determine the relative smallpox immunity of vaccinated and unvaccinated persons.

The Executive Secretary also lists among his activities his visitation of county medical societies, and the stimulation of their members to take up periodic health examinations, and other activities of a semi-civic nature.

The Executive Secretary is responsible for editing the Journal of the State Society. One feature of the Journal has long been the appointment of a "Reporter" for every county medical society. Regarding the work of the county reporters, the Editor says:

"We have succeeded in bringing the publication of County Society reports right up to date and each monthly issue of the JOURNAL now carries the reports of every County Society meeting held during the preceding month, this record has been maintained since February and there is no good reason why it should not be continued indefinitely."

The Editor makes the following report regarding a department on post graduate reading:

"The first innovation attempted in the Journal, and which insofar as I know has never been used in such manner before, was the establishment of the 'Observations from the Lighthouse' an attempt to present monthly a few suggestions for postgraduate reading on some medical topic."

This department in the September issue consists of a three-page review of the Tonsil Question.

The Editor also reports on the establishment of a department called "Esthetics," which the Editor says is "Devoted to the relationship between medicine and the other arts and sciences, to the end that the physician shall not permit himself to become entirely detached from the rest of the thinking world nor entirely submerged in his own affairs."

This department in the September issue consists of a scientific poem on the cellular development of man.

The Executive Secretary also reports on another new department, that of Medical Economics, which in the September issue consists of a sermonette on "Enjoying One's Job."

The New Jersey State Medical Society defends its members against malpractice suits, partly by providing the counsel, and partly through co-

operation with a company that furnishes indemnity insurance. Only a minority of the members carry indemnity insurance.

The State Medical Society favors the group insurance plan by which each member will take indemnity insurance in a specific insurance company. The Committee on Medical Defense reported:

"Since this insurance has been in force, there have been issued 1,387 certificates to different members. Last year there were issued 582 certificates, and out of 2,200 members or thereabouts there are only 582 who are now insured under this Group Plan. The rest of the members are still operating under the old Medical Defense plan. The Chairman of the Judicial Council has drawn attention to this in his report and has urged the necessity of having all the members take out the group insurance policies.

"Perhaps the members of this Society are not as yet cognizant of the fact that under the old form of medical defense, that is, the form which existed before this insurance scheme went into effect, the doctors are not protected excepting to the extent of \$250 in the lower court. Now we have had some experiences of that kind, and I don't think the members ought to rely upon it. They should go into this scheme whereby they can be defended and also be indemnified. The price of this medical defense, or at least the price of the premium is reasonable enough,—it is \$16 for a \$5,000 limit, and \$21 for a \$10,000 limit, and \$27 for a \$25,000 limit. For a man to pay \$27 a year to be protected to the extent of \$25,000 a year must be a great comfort to him."

The Committee makes the following recommendations:

"That the members of the Society, who are not insured under the group form of indemnity insurance, avail themselves at once of its advantages.

"That component county societies having independent group contracts be urged to unite with the State Society, such union will result in stronger organization for medical defense and reduction in the cost of insurance."

Regarding malpractice suits, the Chairman of the Judicial Council says:

Your Council has been impressed with the number of suits started or threatened against our members. We have also observed that these cases are generally against the best practitioners and many of them started after an attempt has been made to collect a long standing bill. We feel that the present medical defense plan of our State Society is not only inadequate but also misleading to the members. Your Judicial Council is almost helpless in the matter of doing anything to aid. We are of the opinion that some new plan of medical defense should be adopted. Each and every member of the Society should protect himself with a policy that will cover his needs.

"We should caution our members not to do anything that will aid and abet in the starting of a suit against a brother practitioner, because a careless remark is often the cause of much trouble."

The Chairman also suggests cooperation of each County Medical Society with the County Bar Association in the hope of obtaining an informal tribunal of lawyers and physicians which would weed out unworthy cases.

A sub-committee on medical expert testimony reported in favor of an expert appointed by the court to testify regarding the medical aspects of a case.

The State Society is interested in reciprocity with Pennsylvania in the recognition of hospitals for the training of internes in order to qualify them for taking the State Examinations.

It is also interested in the Board of Examiners for licensing medical practitioners and is also planning an extensive system of Graduate Medical Education. (See adv. page xiv.)

The rules of the New Jersey State Society evidently impose the penalty of suspension from the State Society or county medical societies for those that fail to send their State dues within a specified time. This rule gave rise to considerable discussion in the Annual Meeting.

In general, the doctors of New Jersey are wrestling with the same problems that their New York confreres are considering. While the methods differ somewhat in the two States, the final results are similar.

# NEWS NOTES

## THE MEDICAL SOCIETY OF THE COUNTY OF QUEENS

A regular meeting of the Medical Society of the County of Queens was held Tuesday, October 27, 1925, at the Eagle Palace, Jamaica, the President, Dr Courten, in the chair. The President announced the appointment of a Committee to revise the by-laws, consisting of Dr Chalmers, Chairman, Drs Keet, Boettiger, Smith and Lavelle, and a Committee on nominations of officers, consisting of Dr F G Riley, Chairman, Drs Whelan, Distler, Barber and Howard. Notice was also given to amend the by-laws so as to provide for the election of a Secretary and a Treasurer. The following candidates were elected to membership.

Drs Thomas M D'Angelo, Abraham Herzog, Theodore Lint, Johnston MacLeod, David Matus, Frederick Grantham Meynen, Thomas S Morton, W J Quinn, William J Smith, T Raymond Surber, Nathan Uris, and Dr Benjamin D Reuben was received by transfer from the Medical Society of the County of Oneida.

Dr F G Riley reported for the Committee on Graduate Medical Education, that arrangements had been made for Friday afternoon lectures twice a month, and that plans were under way for the announcement of clinical courses to be offered at the various hospitals in the borough.

By direction of the Comitia Minora the secretary read four communications from Dr S D Hubbard, of the Division of Illegal Practice of the Department of Health, concerning investigations of the several alleged illegal physicians in the Borough of Queens.

The Committee on nominations announced the following nominations:

For President, Denis E McMahon, Vice President, Joseph S Thomas, Secretary, Ernest E Smith, Treasurer, James M Dobbins, Censors, Henry C Eichacker, Wilham J Lavelle, Walter C A Steffen.

Delegates to State Society: Denis E McMahon, Ernest E Smith, Carl Boettiger.

Alternate Delegates to State Society:

William H Jessup, W Guernsey Frey, Jr, Thomas P McCann, James R Reuling, Charles W Martin, Henry C Eichacker.

In Scientific Session, the society met jointly with the Queensboro Tuberculosis Association. Dr Herman Robbins read a paper on the "Control of Malnutrition in School Children." The

paper was a brief report of careful, painstaking work done by Dr Robbins with a special Class of about 100 malnourished children in one of the city schools. As a result of the work which consisted in weekly nutrition class sessions, with parents in attendance, reports by children on food taken, lunches at school, rest periods at school and at home, the group of children gained in weight on average 4.6 times the average weight gained in a control class of the same number of children.

An interesting discussion followed in which Dr Carl Laws, Professor of Pediatrics, Long Island Hospital Medical College, Dr Charles Prest, Secretary, Queensboro Tuberculosis Association, Dr M M Vinton, Dr W C A Steffen, and Dr L M Rohr took part.

Dr Foster Murray in his paper on "Collapse Therapy in Pulmonary Tuberculosis: Its Indications and Limitations," pointed out that the various procedures used are intended to promote rest to the lung involved. Types of cases suitable for Artificial Pneumothorax are: (1) Chronic Progressive cases which fail to improve under rest, i. e., clinical symptoms persisting as do the physical signs and radiographical findings. (2) Cases with caseation and cavitation. (3) Caseous tuberculous pneumonia and bronchopneumonia. (3) Cases where because of economic or emotional conditions, time is important. (5) Cases that improve under other treatment, but are not cured. In these cases the treatment is given for from 2 to 5 years, depending upon the type of case and consists in the introduction of filtered sterile air into pleural cavity, so that the lung is compressed. A contra-indication to the treatment is active lesions of considerable extent in opposite lung. Among the limitations of the treatment are the occurrence of adhesions and fluid.

More radical measures considered are phrenotomy and thoracoplasty.

After the reading of the papers, Dr W W Britt, Chairman of the Committee on Economics of the Medical Society of the State of New York, spoke briefly on the nursing problem, periodic health examinations and Workmen's Compensation Law.

After a vote of thanks to the speakers of the evening, the meeting adjourned. Collation followed. Attendance 90.

## MEDICAL SOCIETY OF THE COUNTY OF NIAGARA

The Annual Meeting of the Medical Society of the County of Niagara was held Tuesday, November 10th, at the Tuscora Club, Lockport

The Meeting was called together by President Schnell, and the minutes of the last meeting were read and accepted

The Annual reports of the officers and committee heads were read and accepted

The following officers were elected for 1926 President, H W Cramer of Lockport, Vice President, Frederick Leighton, Secretary-Treasurer, G L Miller, Censors, C W Clendenning, F A Walden, R P Barry, Delegates to State Society, W A Peart, F J Schnell

The following applications for membership were presented, favorably acted upon by the censors, and they were voted members of the Society Drs Jennie E. Mabey, Jesse R. Harris, Duane C Johnson, Guy P Philbrick, Irwin M Walker

The membership expressed a desire to hear

from the State Society the exact position of our state malpractice insurance with special reference to the need for the increase in premiums, the position of commercial companies in the State, and the relationship between the State Council and these private companies, in case of suit of a member carrying commercial insurance.

A plan for the prosecution of irregular practitioners was discussed at some length and referred to the Censors for consideration

Dr Britt, Chairman of the State Society's Committee on Medical Economics, was introduced as the speaker Dr Britt gave a practical and explicit talk on the aims of his committee in regard to the subject of "Periodic Health Examinations of the Well"

The discussion upon this subject was so voluminous and divergent as to undoubtedly convince Dr Britt that his talk was interesting, and his subject vital in the opinions of the general practitioner

---

## MEDICAL SOCIETY OF THE COUNTY OF SULLIVAN

The first lecture of a post graduate course for the Medical Society of the County of Sullivan was given in Liberty on November 11, by Dr Samuel Tirman of the Long Island College Hospital, Brooklyn Dr H M Pointexter, Secretary of the Society, sent out a descriptive appeal to the members, and says

"The course is organized and conducted by the Medical Society, your own organization It does not come from above It is not a paternal arrangement It is your own society, therefore we expect you to share and receive all the benefits it offers you, and we also expect those that are not members of the County Medical Society to see this thing in the proper light, and we urge them and expect them to enroll in the Sullivan County Medical Society, a social, scientific, economic society for their benefit and for their use

"Wednesday, November 11, the first course will be given on cardiology The lecturer and instructor will be Dr Tirman of the Long Island College Hospital Multiple stethoscope will be utilized, so that while Dr Tirman examines a pa-

tient and explains the various adventitious sounds of the heart, all physicians present can listen in at the same time

"We ask all the members of the County Medical Society, as well as physicians, non members, but residing in the County of Sullivan, to bring their patients suffering from heart disease to this clinical course Dr Tirman will examine your patient, give diagnosis and treatment You and your colleagues will be greatly benefited by it, and still more your patient"

The afternoon was devoted to a clinic on hearts, and the multiple stethoscope enabled all the doctors to listen at the same time, and the demonstrator to be sure that the sounds were actually being delivered by the instrument.

The evening program consisted of a black-board talk and demonstration in cardiology Over twenty doctors were in attendance The President of the Society, Dr Rayevsky, is planning other lectures in cooperation with the Committee on Education of the State Society

---

## MEDICAL SOCIETY OF THE COUNTY OF CATTARAUGUS

The bi-monthly meeting of the Medical Society of the County of Cattaraugus was held in the Masonic Parlors, Salamanca, November 10, 1925

The Committee, Drs W B Johnston, M C Hawley, J Z Gaston, J E K Morris and S H Bennett on Post graduate Medical Instruction, which was appointed at the meeting held September 8th, reported in favor of the plan The report was unanimously adopted and the matter was

referred back to the Committee to make the necessary arrangements with the State Society

Dr Frank H Richardson of Brooklyn gave a very interesting and instructive address on "Infant Feeding" The doctor's address was brimful of practical suggestions and facts gathered from his large experience in dealing with babies The members of the society expressed their keen appreciation of the address

# THE DAILY PRESS

The New York *Herald-Tribune* has recently printed a series of accounts of the arrest of a dealer in hashish, and of his disclosure that he obtained the drug from plants growing in the midst of New York City. The items suggest thoughts along the lines of history, philology, and economics as well as of toxicology.

Hashish is under the ban of the police because it is a narcotic poison. It is widely used in India and Arabia by smoking or as a confection, in order to produce a nervous excitement which is usually accompanied by pleasing visions. It is peculiarly adapted to the contemplative tastes of the Eastern people, for it produces an enormously prolonged sense of time, so that a minute seems a whole day. Another peculiarity of the delirium is that its form may be directed to a great extent, along lines of wealth, for example, or sensual gratification. This fact was utilized by Arab robber chiefs who gave their followers hashish, in order to excite them to murder. The English word "assassin" comes directly from the Arabic *hasheesh*, and carries with it a volume of history of robberies, murders and feuds in the Arabian deserts.

The word "hashish" in Arabic means hay, and suggests that the old Arabs had a sense of humor very much like that of the modern American who says that his favorite brand of tobacco composed largely of hay.

Hashish was known as a narcotic in the most ancient days of history. It is called *Cannabis indica* in the pharmacopeia. The word "cannabis" in ancient Greek goes back through the Persian and Sanskrit to the most ancient languages. Coming down toward modern times, the same word with changes which follow well known etymological laws comes down through the Russian and the Balkan languages, and appears in the Anglo Saxon as "henep," and in modern English as "hemp." This is an example of a considerable number of words such as god, father, house and cow that help to prove the ancient Aryan origin of modern European people.

*Cannabis indica* is the hemp plant from whose inner bark rope is made. It was one of the earliest sources of coarse cloth. Our word "canvas" is "cannabis" slightly changed, and "to canvass" originally meant to sift through a sieve of coarse canvas, hence to examine carefully.

Hemp will grow in almost every land in the temperate zone, and was extensively grown in the Middle West, until cheaper sources of cordage fibre were available. It will also grow wild on rubbish heaps, in which case it probably springs from waste hemp seed fed to canary birds.

The newspaper reports state that the prisoner arrested in New York led the police to his source of supply in plants growing in old rubbish heaps in the Sunnyside yards of the Pennsylvania Railroad in Long Island City. A few plants were a gold mine to the prisoner, who made cigarettes from the leaves and sold them at a dollar apiece.

It is not at all strange that poisonous plants should be found on rubbish heaps and other waste places in cities and villages. *Stramonium* is a big branching plant that belongs to the *belladonna* family, and grows in profusion in nearly every old barnyard and rubbish heap. It has often caused death, and was formerly smoked for the relief of asthma. Patches of *belladonna* itself are often found sprawling over the grasses by the seaside. The big branching plants of *hemlock* are common in fence corners, and the deadly *veratrum viride* is abundant in some swamps, looking like tall plants of skunk cabbage.

The *Herald-Tribune* of November 7th quotes Dr. Carleton Simon as follows:

"Although it is the oldest of all habit-forming narcotic drugs, its cultivation and sale are not prohibited by the Federal Harrison drug act. Except for medicinal purposes, however, its distribution is forbidden by ordinances in this city and some other cities and localities, such as Massachusetts, California and Dallas.

"That it is a great danger," commented Dr. Simon, "is fully recognized by the Mexican government, which has legislated against it, but, strangely enough, not by our own. In the Mexican underworld and throughout our Southwest the dried *cannabis indica* leaves are used in the form of cigarettes, a few drafts of which will stupefy the unaccustomed. It produces a feeling of lightness and puts the addict into a sort of ecstasy. This is followed by hallucinations and then comes a sleep of a dozen hours. After this the hashish user awakens with a dreadful headache, nausea and a desire for more of the drug.

"A variety of effects follow each other rapidly then, so rapidly, indeed, as to produce a sense of great prolongation of time. Ten minutes, for instance, will seem to the addict like a long hour filled with agreeable sensations. It produces a sort of double consciousness, and gives small spaces the semblance of tremendous proportions. The habit of taking this drug is very quickly formed, and it is specially productive of criminal tendencies. Confusion of thought and abnormal inclinations appear, ultimately driving its users insane."

## EUTHANASIA

News items from a small town in Colorado have described the trial of a doctor for chloroforming his daughter, thirty-four years old, who was an imbecile from birth,—blind, deaf, dumb, nearly paralyzed, and subject to convulsions. The particular reason given by the father for his act was that he was in poor health and feared that he could no longer give his daughter proper care. He seems to have had an unreasoning abhorrence of his daughter becoming a public charge.

The trial resulted in a disagreement of the jury, which stood 11 to 1 for acquittal. The Brooklyn Eagle, November 13th, says editorially: "Nearly everybody who has watched the case wonders not that Dr. Blazer goes free, but that he was not acquitted with flying colors. Society has no desire to punish such a man as Dr. Blazer. But society has a distinct reason for making euthanasia killings infrequent."

These editorial sentiments seem to be shared by the members of a church in Denver, who, according to an Associated Press report, voted in favor of euthanasia on a brother member, a prominent man who has an incurable disease and wishes to die. The bishop of the church announced that the vote was an official act of the church, and was based on love and affection for the sufferer.

The attitude of both the newspaper and the Denver church is opposed to that of physicians. Euthanasia is a cowardly way of escaping responsibility, and physicians cannot admit its justification.

It is one thing to express a wish that death might remove the burden of pain and care from an incurable sufferer and his family, it is quite another thing to summon the aid of death. Medical science provides other means for relieving suffering. Physicians consider it a privilege as well as a duty to administer sedatives which effectively relieve pain and suffering, and they are always ready to cooperate with the clergy in applying the consolations of the church, and to add their own words of encouragement and comfort. They will ease the latter days of the sufferers, but they will never hasten the coming of the Angel of Death.

Society as well as physicians will not sanction euthanasia in any form. What is the alternative? It is evidently that society should provide the means for caring for the imbeciles and the incurables who are great burdens to their families. Modern sciences, and sociology are perfectly sufficient to provide institutional care whose comforts exceed those available in the best homes. The promotion of these institutions is the doctor's answer to the question of the infliction of euthanasia.

## MEASURING THE SOUL

One report of the trial of the euthanasia case stated that a possible line of defense to be offered

was that the imbecile victim had no soul, and was therefore not a human being. On the same day the newspapers carried a story that a French scientist had measured the soul. These incidents bring up the question, what is the soul?

The popular as well as the scientific and medical conception of man is that he is composed of two elements, body and soul. We know the body, or physical part of our being, by means of its effects on our senses. Whatever affects our senses is physical. All knowledge is founded on impressions received through the senses. Experiments in proof of the existence of the soul are attempts to record impressions of the soul on our physical senses, which are imperfect and are adapted to receive only a small range of impressions which other animals seem to receive. A dog, for example, has its power of scent highly developed, and an ant seems to gain information by a means of a highly developed sense of feeling in its feelers.

What the Frenchman seems to have done is to measure some kind of electrical emanation from the body, and after allowing for all known sources of influence, he concluded that what is left is the soul.

Other experimenters have attempted to photograph the soul at the instant of its flight from the body, and they get a ghostly smudge which they interpret as the picture of the soul.

As the receptive powers of man's senses are increased by the telescope, the spectroscope, the microscope, and the radio, so does he penetrate into the physical depths of what was formerly interpreted as the exclusive realm of the spiritual soul. We can be certain that whatever we can see, or measure, or handle is not the spiritual part of our being. It may be that, if man had a dog's acute sense of smell and the ant's sense of touch, he could penetrate even further into the unknown physical world, but he would not be any nearer to the recognition of the soul.

## SEEING WITH THE SKIN

The New York Sun, November 10th, announces that a French scientist has discovered four girls who have skins so sensitive that they can read ordinary books by means of their sense of touch while their eyes are blindfolded. Similar reports elsewhere are vague and indefinite, and state conclusions only. The opportunities for error and wrong interpretations are numerous, and when the experiments are repeated by trained investigators, the subjects fail to perform their wonders.

Newspaper reports of reading by means of the skin appear every few months. They come from so-called scientists who are not medical men or even psychologists, and they are usually ascribed to foreign sources, the farther they are away, the better chance have the reports to survive.

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this columns will be made for review, as dictated by their merits, or in the interest of our readers.

- THE NERVOUS CHILD** By HECTOR CHARLES CAMERON, M.A., M.D., F.R.C.P. Third Edition 12mo of 233 pages, with 8 illustrations London, Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$2 30 (Oxford Medical Publications)
- DISEASES OF THE HEART** By SIR JAMES MACKENZIE, F.R.S., M.D., F.R.C.P. Fourth Edition Royal octavo of 496 pages with 342 illustrations London, Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$9 00 (Oxford Medical Publications)
- THE EARLY DIAGNOSIS OF THE ACUTE ABDOMEN** By ZACHARY COPE, B.A., M.D., M.S., Lond., F.R.C.S., Eng Third Edition. Octavo of 233 pages with 28 illustrations London, Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$3 80 (Oxford Medical Publications)
- THE HISTOLOGY OF THE MORE IMPORTANT HUMAN ENDOCRINE ORGANS AT VARIOUS AGES** By EUGENIA R. A. COOPER, M.D. Octavo of 119 pages, with illustrations London, Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$4 00 (Oxford Medical Publications)
- COMMON DISORDERS AND DISEASES OF CHILDHOOD** By GEORGE FREDERIC STILL, M.A., M.D., F.R.C.P. Fourth Edition Octavo of 965 pages with illustrations London, Humphrey Milford, New York, Oxford University Press, 1924 Cloth, \$7 50 (Oxford Medical Publications)
- NEUROLOGICAL FRAGMENTS** By J HUGHLINGS JACKSON, M.D., F.R.S., F.R.C.P. With Biographical Memoir by James Taylor, M.D., F.R.C.P. and Including the "Recollections" of the late Sir Jonathan Hutchinson and the late Dr Charles Mercier Octavo of 227 pages London, Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$3 75 (Oxford Medical Publications)
- PRACTICAL OBSTETRICS** By E. HASTINGS TWEEDY, M.D., F.R.C.P.I. and G T WRENCH, M.D., in collaboration with BETHEL SOLOMONS, M.D., F.R.C.P.I. Fifth Edition. Octavo of 617 pages with 159 illustrations London, Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$6 25 (Oxford Medical Publications)
- LIVING ORGANISMS An Account of Their Origin and Evolution.** By EDWIN S GOODRICH, F.R.S. 12mo of 200 pages with illustrations London, Clarendon Press, New York, Oxford University Press, 1924 Cloth, \$2 00
- CHILD HYGIENE.** By S JOSEPHINE BAKER, M.D., Dr P.H. Octavo of 534 pages New York and London, Harper and Brothers, 1925 Cloth, \$5 00 (Harper's Public Health Series)
- THE DEGENERATIVE DISEASES Their Causes and Prevention** By LEWELLYS F BARKER, M.D and THOMAS P SERUNT, M.D Octavo of 254 pages New York and London, Harper and Brothers, 1925 Cloth, \$4 00 (Harper's Public Health Series.)
- SOCIAL PSYCHOLOGY** By KNIGHT DUNLAP Octavo of 261 pages. Baltimore, Williams and Wilkins Company, 1925 Cloth, \$4 00
- ARTIFICIAL SUNLIGHT AND ITS THERAPEUTIC USES** By FRANCIS HOWARD HUMPHRIES, M.D (Brux.), F.R.C.P (Edin.), M.R.C.S (Eng), L.R.C.P (Lond.), L.M (Rot., Dublin), D.M.R. and E (Cantab) Second Edition. Octavo of 201 pages with illustrations. London, Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$2 75 (Oxford Medical Publications)
- RADIUM Its Therapeutic Uses in General Practice.** By G H. VARLEY, M.D (Oxon) 12mo of 103 pages. London, Humphrey Milford, New York, Oxford University Press, 1924 Cloth, \$1 75 (Oxford Medical Publications)
- THE CHEMICAL AND PHYSIOLOGICAL PROPERTIES OF THE INTERNAL SECRETIONS** By E. C. DODDS, Ph.D., B.Sc., M.B., B.S. and F DICKENS, M.A., Ph.D. Octavo of 214 pages London, Humphrey Milford, New York, Oxford University Press, 1925 Cloth, \$2.50 (Oxford Medical Publications)
- THE NURSING OF EYE CASES** By LOUISE KINGHAM, S.R.N. 16mo of 16 pages London, Humphrey Milford, New York, Oxford University Press, [1925] Paper, \$30
- HISTORY OF MEDICINE.** By Dr MAX NEUBURGER. Translated by ERNEST PLAYFAIR, M.B., M.R.C.P., in two volumes Vol 2, Part 1 Octavo of 135 pages London, Humphrey Milford, New York, Oxford University Press, 1925 Paper, \$2.25 (Oxford Medical Publications)
- DISEASES OF THE NOSE, THROAT AND EAR, MEDICAL AND SURGICAL.** By WILLIAM LINCOLN BALLENGER, M.D. Revised by HOWARD CHARLES BALLENGER, M.D. Fifth Edition. Octavo of 1080 pages, illustrated with 551 engravings and 32 plates Philadelphia and New York, Lea and Febiger, 1925 Cloth, \$10 00
- THE INTERNAL SECRETIONS OF THE SEX GLANDS The Problem of the "Puberty Gland"** By ALEXANDER LIPSCHÜTZ, M.D. With a Preface by F H. A. MARSHALL, F.R.S. Octavo of 513 pages, with 142 illustrations Baltimore, Williams and Wilkins Company, 1924 Cloth, \$6 00
- THE MEDICAL ASPECTS OF CHEMICAL WARFARE.** By EDWARD B VEDDER, Lieut. Colonel, M.C., U.S.A. With a chapter on the Naval Medical Aspects of Chemical Warfare, by DUNCAN C. WALTON, Lieut. Commander, M.C., U.S.N. Octavo of 327 pages Baltimore, Williams and Wilkins Company, 1925 Cloth, \$6.50
- PRACTICAL PHYSIOLOGICAL CHEMISTRY** By SYDNEY W COLE, M.A. Sixth Edition. Octavo of 405 pages. Baltimore, Williams and Wilkins Company, 1920 Cloth, \$4 00

- AN APPROACH TO SOCIAL MEDICINE.** By FRANCIS LEE DUNHAM, M.A., M.D. Octavo of 242 pages Baltimore, Williams and Wilkins Company, 1925 Cloth, \$4 00
- VITAL CAPACITY OF THE LUNGS A Handbook for Clinicians and Others Interested in the Examination of the Heart and Lungs Both in Health and Disease.** By J A. MYERS, M.S., Ph.D., M.D. Octavo of 140 pages Baltimore, Williams and Wilkins Company, 1925 Cloth, \$3.25

# BOOK REVIEWS

**GYNÉCOLOGY WITH OBSTETRICS** A Text-Book for Students and Practitioners By JOHN S FAIRBAIN, M.A., B.M., B.Ch., F.R.C.P., F.R.C.S. Octavo of 769 pages, illustrated. Cloth, \$8.00 London, Humphrey Milford, 1924 (Oxford Medical Publications)

This text-book is unique in that within its covers one may find all the essential facts of gynecology and obstetrics. Stressing the importance of a knowledge of midwifery as essential to the practice of gynecology the author quotes "The obstetrician and gynecologist is the great example of the unity of medicine and surgery in actual practice. Here is the full integration."

Though frankly a text-book, there is a very interesting historical review, and a plea for recognition of midwifery as a branch of Preventive Medicine of great importance. All our text-books on obstetrics might well carry similar chapters. The book is well done, and particularly valuable for the student who desires to find a large amount of information in what the author calls, "water tight compartments" C. A. G

**HIRSCH'S "COMPEND OF GENITO-URINARY DISEASES AND SYPHILIS,"** Including their Surgery and Treatment. 4th Edition Revised. 44 illustrations. Cloth, \$2.00 By CHARLES S HIRSCH, M.D., Urologist to the Jewish Hospital, Mt. Sinai Hospital, and Eagleville Hospital for Consumptives. Out Patient Dept., Philadelphia. P. Blakiston's Son and Co., Philadelphia, 1924

This fourth edition of a concise and comprehensive work is brought up to date. It is intended primarily for the student or for the busy practitioner who has no easy access to a library for reference. A list of one hundred questions are appended for the student's use.

AUGUSTUS HARRIS

**AN INTRODUCTION TO PRACTICAL BACTERIOLOGY, AS APPLIED TO MEDICINE AND PUBLIC HEALTH** A Guide to Bacteriological Laboratory Work for Students and Practitioners of Medicine. By T J MACKIE, M.D., and J E MCCARTNEY, M.D. William Wood & Company, New York, 1925 Price, \$3.50

This is an excellent handbook of practical bacteriology as it applies to medicine and public health. The authors have arranged the subject matter in accordance with their method of teaching, and the book is easily read and understood.

After a general introduction, the book takes up immunity, an excellent chapter on the microscope, cultivation of bacteria, staining methods, special procedures and examinations, and then specific description and study of the various bacteria. I. COHN

**THE TECHNIC OF LOCAL ANESTHESIA.** By ARTHUR E. HERTZLER, A.M., M.D., Ph.D., LL.D., F.A.C.S. Third Edition. With 140 Illustrations. The C. V Mosby Company, St. Louis, 1925 Price, \$5.50

In writing a book on Local Anesthesia Dr Hertzler has a better than the average equipment in that he has made a special study of anatomy and again that he is a practicing surgeon with opportunity to test various methods

In his discussion of the drugs employed, he emphasizes the use of quinine and urea hydrochlorid, which is at variance with the custom of most men.

The study of the histologic changes in tissue when quinin is used is original and a valuable research.

The body of the book is taken up with a discussion of the best methods of inducing anesthesia for various operations. The use of Regional Anesthesia is not stressed. Operations on the perineum, rectum,

cervix and other operations are described at length under local but might better be done under caudal anesthesia.

On the whole the book is to be recommended, not so much to the beginner but to the man with some experience who is weighing the value of the various procedures S LLOYD FISHER.

**DIABETIC DIET** A Handbook for Diabetics. By A. DORIS MCHENRY, B.A., and MARJORIE M COOPER, B.A. Harper & Brothers, New York. 1925

This is a convenient manual for the use of the patient and the necessary information is presented in an attractive way. The chapter on Diabetic Recipes is comprehensive, covering about twenty-five pages

The book compares favorably with the others of its type and may be recommended as a simple but satisfactory volume W E. MCCOLLOM

**HANDBOOK OF OPERATIVE SURGERY** By SIR WILLIAM IELAND DE C. WHEELER, (Mod.) B.A., M.D., (Dub Univ.), F.R.C.A.S.I., F.A.C.S. (Hon.) Surgeon to Mercer's Hospital and the National Children's Hospital, Dublin. Fourth Edition, William Wood & Company, New York, 1925 Price, \$5.50

This fourth edition is a small volume well adapted to the need of students or practitioners who are preparing for examinations in operative surgery. It is also of value to the general practitioner for the purpose of acquainting himself with the varied types of procedure adaptable in surgical positions.

Original ideas of the author in the treatment of various conditions have been incorporated in the work.

The book is brought up to date by the addition of text on surgical questions which are the subject of discussion today HARRY KOSTER.

**HANDBOOK OF BACTERIOLOGY** For Students and Practitioners of Medicine. By JOSEPH W BIGGER, M.D., (Dublin), F.R.C.P.I., D.P.H., William Wood & Company, New York, 1925 Price, \$5.00

This addition to the text books on bacteriology can hardly be said to hold any unique position on a subject already so well covered by good texts of a like nature. The reviewer's impression of this text book is that brevity has been carried to an extreme. The book does, however, fulfil the author's aim, in that he has included and condensed, somewhat dogmatically, as he admits, most important topics, theories, and bacteria essential to an elementary understanding of bacteriology and immunity by a medical student.

The text is written in a brief, yet lucid style, amply and remarkably well illustrated by drawings, photographs and colored plates.

An outstanding feature of the book is the correlation between the various pathogenic organisms and the corresponding lesions produced in the animal organism.

S D KRAMER

**THE PRACTICAL MEDICINE SERIES**, comprising eight volumes on the year's progress in medicine and surgery Vol IV, Pediatrics, edited by ISAAC A. ABT, with the collaboration of JOHANNA HEUMANN, M.D. Series 1924 The Year Book Publishers, Chicago, Ill. Price, \$2.00

This little book deserves the highest commendation from every one interested in Pediatrics as a specialty, for the vast amount of readily accessible information it offers in such compact form.

Considering the numerous articles that find their way into press both at home and in the foreign literature, it is no easy matter to judge which material shall be

included and which omitted from a "collection of information which reflects the year's progress in Diseases of Children"

Among numerous other brief reports one finds here such helpful and "up to the minute" excerpts from studies on Diabetes, Goiter and Tuberculosis to more than justify its recommendation to one's Pediatric library. The chapter on Tuberculosis is quite complete and true to the style of its distinguished Editor, reads like an enchanted detective story, without sacrificing any of its scientific data. Of special mention in this connection is the paragraph on the Radiologic aspect of this ever new and baffling subject.

Followers of the ultra modern school will find "all the news that's fit to print" on such subjects as the Intravenous injections of Mercurochrome in the treatment of Pneumonia, also reference on Diathermy as a remedy for Pneumonia. The Editor's warning comment on these two remedies is highly endorsed.

It is delightful to find the detailed report of Zingher's study with the Dick test on normal individuals, also his work on measles. Quite naturally, recent studies on Infant feeding as well as breast feeding occupy a prominent part of the book.

He who has followed the Pediatric literature regularly will find this publication a handy and ready reference. He who for some reason or other, may have to "catch up" with the times, will surely find this little book a boon.

HARRY APFEL.

**MEDICAL EDUCATION, A COMPARATIVE STUDY** By ABRAHAM FLEXNER. The Macmillan Company, 1925. Price, \$2.50.

Actually a survey of medical education, but written in a most engaging way, and without the dry details ordinarily found in such a study, this book is a welcome addition to our critical literature. Stressing the fact that "Medical education cannot be described or discussed apart from general education," there is implied criticism of secondary education in this country. This is the important feature, although as a comparative study of medical education here and abroad, the book is comprehensive, well worth while, and very well done.

C. A. G.

**PROCEEDINGS OF THE INTERNATIONAL CONFERENCE ON HEALTH PROBLEMS IN TROPICAL AMERICA.** Held at Kingston, Jamaica, B. W. I., July 22 to August 1, 1924. By Invitation of the Medical Department United Fruit Company. Published by United Fruit Company, Boston, Mass., 1924.

This volume of the proceedings of the International Conference on Health Problems in Tropical America, held at Kingston, Jamaica, B. W. I., July 22 to August 1, 1924, by invitation of the Medical Department of the United Fruit Company, is a storehouse of information concerning not only the diseases common to the tropics but also contains articles on many conditions of disease present in more temperate climates. Carefully prepared papers on preventive medicine, tropical medicine, malaria, blackwater fever, yellow fever, intestinal parasites and the dysenteries, leprosy, pellagra, hookworm, tropical dermatology, the use of serums and other subjects are presented by men of international reputation in their subjects. No single book of recent publication contains so much on tropical disease as this volume, which has been made possible through the invitation and cooperation of the United Fruit Company. The discussions of the various papers contain comments upon the practical

aspects of the topic under discussion by the men working in different parts of the world and add materially to the value of these papers. The book is well printed and the illustrations are accurate and excellent. This publication is a valuable addition to medical literature.

HENRY M. MOSES

**THE DIAGNOSIS OF CHILDREN'S DISEASES, WITH SPECIAL ATTENTION TO THE DISEASES OF INFANCY.** By Professor Dr. E. FEER, Director of the University Children's Clinic, Zurich, Switzerland. Translated by CARL AHRENDT SCHERER, M.D., F.A.C.P. J. B. Lippincott Company, Philadelphia, 1925. Price, \$5.00.

The translation of this book into English for the first time adds a volume to the encyclopedia of pediatrics in this country that will be welcomed. To those who desire to stimulate their diagnostic acumen at the bedside of the sick infant or child and not rely so much on the laboratory, this work will be found immensely helpful. In other words, it is a book that deals with symptoms, not even differential diagnosis per se is stressed.

Professor Feer is one of the foremost teachers of pediatrics in Europe and this book is written in the style that he teaches. The most prominent symptom of a case is pointed out and the diagnosis is developed from it, laboratory methods being used only as a last resort. The text is supplemented by numerous illustrations from his own cases of the symptoms described.

THURMAN B. GIVAN

**METHODS AND PROBLEMS OF MEDICAL EDUCATION (First and Second Series),** Division of Medical Education, The Rockefeller Foundation, New York, 1924.

These new studies fill a long felt need. It is apparently the intention of the Foundation to publish from time to time contributions to Medical Education, which may be too long for the average journal, possibly of interest to only a limited group, yet of prime importance in the progress of medical education.

The first volume is devoted to teaching methods and physical plans of some of the great medical schools here and abroad, while the second deals with the sanitary survey. The text is English, French and German. Both volumes are intensely interesting.

C. A. G.

**RETINAL VENOUS THROMBOSIS. A Clinical Study of Sixty-two Cases Followed Over Many Years.** By R. FOSTER MOORE. Octavo of 90 pages. London, Geo. Pulman & Sons, 1924. Paper. (Forms Supplement No. 2 of the *British Journal of Ophthalmology*.)

Foster Moore has made one of those rare contributions to Ophthalmology which justly deserves the title of "contribution."

Anyone who has attempted to make a minute and detailed study of fundus changes over a long period of time for a single case with the object of collecting data realizes what a tremendous undertaking it is.

The painstaking and detailed manner in which Foster Moore has undertaken this clinical research places it among the highest types of investigations in any field of science. He takes his analysis up under particularly appropriate headings, as symptoms, causes of thrombosis, changes in veins after thrombosis, retinal hemorrhages, retinal exudates, visual acuity, visual fields, intraocular tension, acute glaucoma, evidences of obstruction without thrombosis and life prognosis.

Altogether, it is felt that every ophthalmologist should add this monograph to his library if he has any ambitions to be properly equipped to interpret the medical aspects of his subject.

## OBSERVATIONS ON THERAPEUTIC VALUE OF SCARLATINAL ANTITOXIN \*

FRANCIS G BLAKE, M.D., and JAMES D TRASK, M D

NEW HAVEN, CONN

IN previous reports <sup>1,2,3</sup>, on the therapeutic value of scarlatinal antitoxin presented in 1924, it was stated that the antitoxin produced a local blanching of the rash at the site of an intracutaneous injection in patients with scarlet fever, that it promptly neutralized the toxin and established an excess of antitoxin in the blood of patients following intramuscular injection in therapeutic doses, and that it appeared to bring about a rapid cure of the disease, as shown by a critical fall of temperature to normal and a rapid fading of the exanthem. Similar clinical results have recently been reported by Birkhaug,<sup>4</sup> Dick and Dick,<sup>5</sup> and Park.<sup>6</sup> Further experience now extending over a period of fifteen months has amply confirmed our previous observations, and has also made it possible to define with greater exactness the therapeutic value of the antitoxin in (1) uncomplicated scarlet fever, (2) scarlet fever with septic complications, and (3) post-scarlatinal sepsis. The data concerning the effect of the antitoxin in these three groups of cases will be presented in the first part of this report. In addition an effort has been made to determine as accurately as possible the amount of antitoxin required to cure scarlet fever promptly and with certainty in cases of varying degrees of severity. The observations concerning dosage will be presented in the second part of the paper.

### THERAPEUTIC EFFECT OF SCARLATINAL ANTITOXIN

In order to interpret satisfactorily the therapeutic effect of scarlatinal antitoxin in uncomplicated scarlet fever, in scarlet fever with septic complications, and in post-scarlatinal sepsis, it is necessary to keep in mind that uncomplicated scarlet fever is essentially a specific toxemia caused by a superficial infection of the throat

with *Streptococcus scarlatinae* without significant invasion of the body tissues by the organism, that scarlet fever with septic complications consists of the specific toxemia with an additional local or general invasion of the body by *Streptococcus scarlatinae* or other pyogenic organisms, and that in post-scarlatinal sepsis the specific scarlatinal toxemia has terminated, but the local or generalized infection of the tissues remains. The clinical symptoms caused by the specific toxemia are fever, accelerated pulse, nausea and vomiting, prostration, delirium, enanthem, exanthem and strawberry tongue, the clinical phenomena due to bacterial invasion of the tissues are represented by such conditions as purulent rhinopharyngitis, sinusitis, otitis media, mastoiditis, ulcerative tonsillitis, cervical adenitis, meningitis, arthritis, thrombophlebitis, and septicemia.

The time relationship of the toxic and septic aspects of scarlet fever and the increasing incidence and importance of the septic phase as the disease progresses are shown diagrammatically on Chart I, which has been constructed from data accumulated in the detailed study of over 100 cases of scarlet fever. The duration of the specific toxic phase, which is closely paralleled by the course of the rash, ordinarily varies from four

Chart I Diagram illustrating the presence of toxin in the blood during the specific toxemic phase of scarlet fever in mild to extremely severe cases, the increasing incidence and importance of septic complications as the disease progresses, and the appearance of antitoxin in the blood following the disappearance of toxin and the fading of the rash, even though the septic phase continues.

\* Read at the Annual Meeting of the Medical Society of the State of New York, May 12 1925

From the Department of Internal Medicine Yale University School of Medicine and the Medical Service of the New Haven Hospital.

to seven days but may be somewhat longer in very severe infections. During this period the specific scarlatinal toxin circulates in the blood and its presence can be demonstrated readily as shown by Trask and Blake.<sup>7</sup> Superimposed upon the toxic phase in an increasing proportion of cases as the disease progresses is the septic phase. In the cases studied only one-third of those coming under observation during the first three days of the disease had septic complications when first seen, in most instances relatively mild in nature, while two-thirds of those coming under observation from the fourth to the seventh day had septic complications, in many instances relatively severe. By the end of the first week local or generalized septic processes have become the most important factor in nearly all patients who are still sick and, even though these persist and become more severe, the specific scarlatinal toxemia rapidly terminates as shown by the disappearance of the circulating toxin and clinically by the fading of the rash. Not only does the specific toxemia disappear, but antitoxin may appear in the patient's blood in spite of the presence of severe sepsis and the septic process may continue to advance in spite of the fact that the patient has himself produced sufficient antitoxin to cure the specific toxic manifestations of scarlet fever. Since the fading of the rash parallels the disappearance of the specific toxemia, all patients with septic processes in whom the rash has gone should be considered to be in the stage of post-scarlatinal sepsis.

With the foregoing considerations in mind, it is clear that one must attempt to distinguish between the effect of the antitoxin on the specific toxic phenomena of scarlet fever on the one hand, and its effect on the septic aspects of the disease on the other, since the two processes are of distinctly different nature. If the serum is effective solely by virtue of its antitoxic properties it should promptly cure uncomplicated scarlet fever, it should likewise cure the specific toxic features of complicated scarlet fever but should only indirectly benefit the septic complications, and it should have little, if any, demonstrable effect in post-scarlatinal sepsis. If, on the other hand, the serum possesses both antitoxic and antibacterial properties, it should not only cure scarlet fever itself but also might have a direct curative effect on the septic complications.

**Therapeutic Results in Uncomplicated Scarlet Fever**—During the period covered by this report 57 cases of uncomplicated scarlet fever have been treated with Dochez's unconcentrated antitoxin by intramuscular injection. Of these 2 were extremely severe, 11 severe, 23 moderately severe, and 21 mild, 44 were treated on or before the third day of the disease, 13 after the third day.

All were promptly cured within 12 to 36 hours, irrespective of the severity or duration of the disease at the time of treatment. Chart II illustrates the invariable therapeutic result in uncomplicated cases.

Chart 2 Critical cure of uncomplicated scarlet fever by antitoxin

**Therapeutic Results in Scarlet Fever with Septic Complications**—Forty-eight cases of scarlet fever with septic complications have been treated. Of these 10 were extremely severe, 18 severe, 13 moderately severe, and 7 mild, 22 were treated on or before the third day, 26 on or after the fourth day of the disease. Purulent rhinopharyngitis with or without sinusitis was present in 29 patients, suppurative otitis media in 11, cervical adenitis in 11, ulcerative tonsillitis or peritonsillar abscess in 9, mastoiditis in 2, thrombophlebitis and septicemia in 1, other miscellaneous conditions in 9. Forty-seven of these patients were promptly cured of the specific toxic phase of scarlet fever as shown by fall of temperature, rapid fading of the rash and prompt neutralization of the toxin of the blood. Their septic complications were not immediately cured but subsided more or less rapidly depending upon the nature, severity, and duration of the complication. One extremely severe case with purulent rhinopharyngitis, ulcerative tonsillitis, cervical adenitis, thrombophlebitis and septicemia who received a single injection of 40 cc of antitoxin on the fifth day died on the eighth day. Charts III, IV and V illustrate the effect of the antitoxin in complicated cases.

Chart 3 Critical cure of specific toxemia and gradual subsidence of septic complications in toxic and septic scarlet fever

Chart 4 Critical cure of specific toxemia and rapid subsidence of septic complications (otitis media and meningitis) following treatment with antitoxin

Chart 5 Critical cure of specific toxemia in extremely toxic and septic case treated on 7th day

### Therapeutic Results in Post-scarlatinal Sepsis

Seven cases of post-scarlatinal sepsis in whom the rash had completely faded have been treated. In none of these was it possible to demonstrate that the treatment had any influence on the course of the infection. If the serum is effective solely by reason of its antitoxic action, this result was to be expected since the specific toxic stage had passed and the patients, in some cases at least, already had a measurable amount of their own antitoxin circulating in the blood before treatment was administered. Chart VI illustrates the apparent ineffectiveness of the antitoxin in post-scarlatinal sepsis.

Chart 6. Failure of antitoxin in post-scarlatinal sepsis. Note the absence of toxin and presence of antitoxin in patient's blood before treatment

*Incidence of Complications and Sequelæ Following Treatment*—Of the 57 uncomplicated cases 5 subsequently developed complications as follows: mild non-suppurative cervical adenitis late in convalescence 2, otitis media 1, transient fibrinous pleurisy 1, and acute nephritis 1. All recovered satisfactorily. Of the 48 complicated cases 5 developed additional complications not present at the time of treatment. These were non-suppurative cervical adenitis and arthritis 1, otitis media 3, otitis media and mastoiditis 1. All recovered satisfactorily.

### AMOUNT OF ANTITOXIN REQUIRED TO CURE SCARLET FEVER

In view of the therapeutic results reported above and the well-recognized fact that sepsis plays an increasingly important rôle as the disease progresses, it is apparent that the goal to be attained in the treatment of scarlet fever with antitoxin is the prompt neutralization of toxin and simultaneous establishment of a considerable excess of antitoxin in the circulating blood of the patient as early as possible in the disease. The amount of serum required will vary with the size of the patient, the severity of the disease, and the antitoxin content of the serum used. In order to determine the amount of serum necessary to accomplish the desired result, the presence of toxin and antitoxin in the blood before and at intervals after treatment has been determined in a considerable series of cases of scarlet fever of varying ages and degrees of severity treated with ten different lots of serum of varying antitoxin content per cubic centimeter. The intramuscular route of injection, rather than the intravenous, has been employed because the intramuscular route will be more generally used in practice.

The presence of toxin in the patient's blood was determined<sup>†</sup> by the capacity of the patient's serum to produce a local reaction when injected into the skin of susceptible human volunteers, the presence of antitoxin by the capacity of the serum to produce a positive blanching test in patients with scarlet fever. The method of comparing the antitoxin content of different lots of serum was to determine the minimum amount of serum that would produce a positive blanching test. This has been designated the minimal blanching dose. For the sake of comparison with the method of antitoxin standardization advocated by the Dicks<sup>5</sup> and now in general use, the number of minimal blanching doses per c.c. has been translated into the number of skin test doses of toxin neutralized per c.c. and in turn into units per c.c.\* The relative strength of the different lots of antitoxin used is shown in Table I.

\* One unit equals the amount of antitoxin that will neutralize 100 skin test doses of toxin.

TABLE I—TITRATION OF THE COMPARATIVE STRENGTH OF 10 LOTS OF SCARLATINAL ANTITOXIN

Antitoxin Lot	—Titration of M B D—					Minimal blanching doses per c.c.	Skin Test doses of toxin neutralized per c.c.*	Units of antitoxin per c.c.
	01 c.c.	002	0004	00008	000016			
1 Dochez (conc.)	++	++	++	+	±	62,500 +	50,000 +	500 +
2 Dochez (unconc.)	++	++	+	±	—	12,500 +	10,000 +	100 +
3 A-77 (unconc.)	++	±	±	±	—	12,500	10,000	100
4 N Y S (unconc.)	++	±	±	±	—	12,500	10,000	100
5 357-9 (unconc.)	+	+	±	—	—	2,500 +	2,000 +	20 +
6 A-5 (conc.)	++	++	±	—	—	2,500 +	2,000 +	20 +
7 362-9 (unconc.)	++	±	±	—	—	2,500	2,000	20
8 U S (conc.)	++	±	±	—	—	2,500	2,000	20
9 351-9 (unconc.)	++	±	—	—	—	500 +	400 +	4 +
10 373-9 (unconc.)	+	±	—	—	—	500 +	400 +	4 +

\* These tests were not done by the authors, but are believed to be approximately correct within the limitations of the method.

As a basis for comparative study 30 cases treated with Dochez's unconcentrated antitoxin were first studied by this method. From the results which are shown in Table II, it is clear that 30 to 40 c.c. of a serum containing 12,500 + M B D per c.c. given intramuscularly is sufficient to neutralize promptly the toxin and establish an adequate excess of antitoxin in the blood of all mild or moderately severe cases of scarlet fever in both children and adults. In the 12 severe cases studied (Table III) amounts of serum ranging from 40 to 195 c.c. were used, usually in divided doses. Analysis of the results shows that the repeated doses were rarely necessary and that 40 to 80 c.c. in children, 70 to 120 c.c. in adults, of a serum containing 12,500 + M B D per c.c. may safely be considered the maximum doses required in severe cases.

TABLE II—Studies on Dosage in Mild and Moderate Cases of Scarlet Fever Treated with Dochez's Unconcentrated Antitoxin (1 c.c. = 100 + units)

Twenty-one patients have been treated with other lots of antitoxin. The relative strength of the different lots, dosage used, clinical effect, and observations on the presence of toxin and antitoxin in the blood of the patients before and after treatment (determined on 12 of the 21), are shown in Table IV. The results of this study are unequivocal and speak for themselves. They

TABLE III—Studies on Dosage in Severe Cases of Scarlet Fever Treated with Dochez's Unconcentrated Antitoxin (1 c.c. = 100 + units)

show that an antiscarlatinal serum to be therapeutically efficient in reasonable dosage should contain at least 12,500 M B D of antitoxin per c.c. or, in other words, should be able to neutralize at least 10,000 skin test doses of toxin per c.c. which is equivalent to 100 units per c.c. This is ten times as strong as the standard advocated by Dick and Dick.<sup>5</sup> They also show that a serum containing 2500 M B D per c.c. (2000 skin test doses neutralized per c.c. or 20 units per c.c.), which is twice as strong as the standard advocated by Dick and Dick,<sup>5</sup> is of very doubtful therapeutic value, and that one containing 500 M B D per c.c. (400 skin test doses neutralized per c.c. or 4 units per c.c.) is of no value.

TABLE IV—Studies on Dosage with 10 Different Lots of Scarlatinal Antitoxin of Varying Antitoxin Content per Cubic Centimeter of Serum.

Study of the therapeutic value of scarlatinal antitoxin in uncomplicated scarlet fever, in scarlet fever with septic complications, and in post-scarlatinal sepsis has made it clear that the antitoxin in proper amount is a specific and efficient cure for uncomplicated scarlet fever. In scarlet fever with septic complications it likewise promptly cures the scarlet fever itself, but does not appear to have a direct or immediate curative effect on the complications. Even though it does not directly cure the septic aspects of the disease in this group of cases, it nevertheless does unquestionably benefit the complications, at least indirectly, presumably by curing the specific toxemia and thereby placing the patient in a position to overcome even serious complications to which he might otherwise succumb. The effectiveness of the beneficial influence on the complications probably depends in part upon the relative importance of the specific toxemia and of the septic process, and in part upon the nature, duration, and severity of the complication in the particular case at the time the antitoxin is given. It is shown clinically by the more or less rapid subsidence of complications following antitoxin treatment. In post-scarlatinal sepsis, on the other hand, it has so far been impossible to demonstrate that the antitoxin possesses any therapeutic value. It would appear, therefore, that the therapeutic value of antiscarlatinal serum is due largely, if not entirely, to its antitoxin content, rather than to any antibacterial properties which it may possess.

Of almost equal importance is the possible effectiveness of the antitoxin in reducing the incidence of complications and sequelæ in those who have not already developed them at the time of treatment. While subsequent complications have been exceedingly few in the group of cases reported and in no instance of a serious nature, it does not seem wise to express a final opinion in this matter until a much larger series of cases has been treated. The results have been sufficiently encouraging, however, to make it probable that the antitoxin will prove to be exceedingly effective in this respect.

It follows inevitably from the foregoing analysis of the therapeutic action of scarlatinal antitoxin that the only rational procedure is immediate treatment as soon as the diagnosis is made before the septic phase of the disease has developed or assumed a significant rôle. Under these circumstances a critical cure may be expected and the probability that complications will develop is small. In cases in which septic complications are present when the patient is first seen antitoxin should be given at once provided the rash is still present. Under these circumstances a prompt cure of the specific toxic features of scarlet fever may be expected and the complications, if not too serious, will more or less

rapidly subside. It should be emphasized in this connection that, even though the specific toxemia is cured, the temperature may remain more or less elevated because of the complication and that the continued fever should not be interpreted as a failure of the antitoxin to cure scarlet fever itself nor as an indication for additional antitoxin treatment *provided the rash has faded within 24 hours*. As already pointed out, little or no benefit may be expected from use of the antitoxin in cases of post-scarlatinal sepsis after the rash has disappeared. Chart 7 illustrates the therapeutic effect of the antitoxin.

Chart 7 Diagrammatic representation of the therapeutic effect of scarlatinal antitoxin. Lines without arrowheads show the natural course of events in untreated scarlet fever. Lines with arrowheads show the prompt disappearance of circulating toxin and appearance of antitoxin in the patient's blood and the more or less rapid subsidence of complications following treatment with antitoxin.

In order to obtain the best therapeutic results it is essential that sufficient antitoxin be given in one dose, not only to neutralize the toxin in the patient's blood, but also to establish promptly a measurable excess of antitoxin in the circulation. Theoretically this excess should be sufficient to last until the patient develops his own antitoxin. In the studies to determine the amount of antitoxin required to accomplish this result, the conclusions arrived at have been based solely upon the actual demonstration of an excess of antitoxin in the blood of the patients studied and not upon clinical impressions concerning the effect of the treatment on the course of the disease. It is true, however, that the therapeutic result, as was to be expected, coincided with success or failure in establishing an excess of antitoxin in the blood of the patient. The results of the study have led us to the conclusion that the basic therapeutic dose for intramuscular treatment should be at least 3000 units of antitoxin. Since 1 unit is that amount of antitoxin which will neutralize 100 skin test doses of toxin, 3000 units is an amount which will neutralize 300,000 skin test doses of toxin, or 30 c.c. of a serum which neutralizes 10,000 skin test doses per c.c. This figure is in marked disagreement with that advocated by Dick and Dick,<sup>6</sup> who state that an amount of antitoxin which will neutralize 20,000 skin test doses of toxin (200 units or 20 c.c. of

a serum that neutralizes 1000 skin test doses per c.c.) is a therapeutic dose. In our experience, as shown in Table IV, even three to four times this amount of antitoxin has failed to establish consistently an excess of antitoxin in the patient's blood or to exert any demonstrable influence on the course of the disease. On the other hand 3000 units as a basic therapeutic dose, is in exact agreement with the figure reached independently by Park,<sup>6</sup> who used the Dick test as a measure of whether or not sufficient antitoxin had been given in patients treated by him.

In view of the data presented above it is believed that satisfactory therapeutic results will be obtained only when an antitoxin sufficiently strong to neutralize at least 10,000 skin test doses of toxin per c.c. is employed. With antitoxin of this strength the following intramuscular dosage is recommended:

	Mild and Moderate	Severe	Extremely Severe
Children	30 to 40 c.c. (3000 to 4000 units)	40 to 60 c.c. (4000 to 6000 units)	80 c.c. (8000 units)
Adults	40 c.c. (4000 units)	60 to 80 c.c. (6000 to 8000 units)	80 to 120 c.c. (8000 to 12000 units)

#### CONCLUSIONS

1. Scarletinal antitoxin in proper amount is a specific and prompt cure for uncomplicated scarlet fever.
2. It indirectly benefits septic complications during the acute stage of scarlet fever presumably by curing the specific toxemia.
3. It has not been possible to demonstrate that it possesses any therapeutic value in post-scarlatinal sepsis after the rash has faded.
4. To be therapeutically efficient in reasonable dosage an anti-scarlatinal serum should contain at least 12,500 minimal blanching doses of antitoxin per c.c. or be able to neutralize at least 10,000 skin test doses of toxin per c.c.
5. The amount of toxin required to cure scarlet fever promptly and with certainty by intramuscular injection varies from 3000 units to 12,000 units (30 to 120 c.c. of a serum which neutralizes 10,000 skin test doses of toxin per c.c.), depending upon the size of the patient and the severity of the disease.
6. To obtain the best therapeutic results the full amount of antitoxin required in each case should be estimated and given at once as soon as the diagnosis is made.

#### DISCUSSION

DR AUGUSTUS WADSWORTH.—I appreciate the privilege of opening the discussion on Dr Blake's paper, and also welcome the opportunity to report to you the work which we have done toward preparing serum for your use.

At the May meeting of the Association of American Physicians in Atlantic City last year, Dr Blake's report of the treatment of scarlet fever with the Dochez antiscarlatinal serum was so striking and so convincing as to the therapeutic value of the serum in the early stages of the disease that cultures were secured from Dr Dochez and the immunization of horses was started during the summer. About the same time, I wrote Dr Dick for transplants of his culture, hoping to compare the action of the serums produced with these different cultures, but I was unable to secure a transplant of the Dick culture. Our experience, until very recently, has therefore been limited to a study of the Dochez strain and of strains that we have been able to obtain from various sources.

Miss Kirkbride and Miss Wheeler have already presented at the recent meeting in Washington the results of their study of scarlatinal and other strains of hemolytic streptococci. They fortunately discovered that some goats are susceptible to the action of the toxin. This fact has permitted an intensive study of the action of these toxins and of their neutralization by antitoxin, which facilitates greatly the standardization of the scarlatinal antitoxin. The evidence in regard to the action of the serum which Drs Dochez, Blake, Trask and Lynch, and also Dr Birkhaug of Baltimore, have accumulated in the last year, together with the observations of Dr Park at the Willard Parker Hospital, leaves no question as to the efficacy of the serum treatment of scarlet fever in the early stages. The fall in temperature, disappearance of the rash and marked improvement in the symptoms—in short a true crisis—suggest very strikingly that the toxemia is neutralized, as it is in the treatment of diphtheria with antitoxin.

We have gradually accumulated a supply of the serum, and from results of our tests and the reports from Dr Blake, the serum which we have prepared by the method of Dochez is equivalent in potency to his serum. The serum has been available since November, but only in limited quantities. It is now being more generally distributed, chiefly in the larger centers of population and the more important district supply stations. Physicians, however, have not used the serum very generally, and only very few reports as regards its use have as yet reached us. These simply confirm those you have already heard.

I am especially interested in Dr Blake's very lucid explanation of the mechanism of the de-

velopment of scarlet fever infection and the action of the serum the early toxemia, the development of antitoxic immunity in the tissues, together with the later parasitic invasion in septic and complicated cases. This point of view affords a very sound basis for the study of the results of serum therapy as they accumulate. It interests me particularly because after all, the streptococci and pneumococci are so closely related that the study of their infectious processes should be very closely correlated. Thus it is that Dr Blake's observations on the streptococcus infection in scarlet fever in principle parallel the conclusions of experimental studies of pneumococcus infection, and the action of immune serum which I have reported from time to time since 1912, namely, that in pneumonia the disease is largely a toxemia complicated by parasitic invasion, and that the immune serum acts in a manner similar to antitoxin in diphtheria, neutralizing the toxic substances. The longer we study the action of antipneumococcus serum in pneumonia and antistreptococcus serum in scarlet fever, the more apparent will become the antitoxic action of these serums, the prognosis depending upon the character of the parasitic in-

vasion of the incitant. In pneumonia, however, the parasitic invasion takes place immediately, whereas in scarlet fever, according to Dr Blake's observations, it is preceded by a period of toxemia which permits of complete and immediate neutralization by the introduction of the serum. Such treatment may serve to prevent subsequent parasitic invasion, and the development of septic complications which, after it once becomes established, may not yield so readily to serum treatment. Intravenous injection will, of course, yield the most prompt results. The patient, however, should be safeguarded from the danger of anaphylaxis by a careful test of susceptibility to horse serum and desensitization with a small dose of the serum—one-fourth to one-half cc. subcutaneously. Intramuscular injections are absorbed a little more slowly, but the danger of anaphylaxis is less than with the intravenous method. It is doubtful if serum sickness can be avoided. It may well be that the concentration of the serum, which we find amounts to about three to four times, may be of value, but one must realize at the same time that the concentration of protein is considerable, two to three times that of normal serum.

## THE ENDOCRINE TREATMENT OF MENSTRUAL DISORDERS \*

TIMOTHY F DONOVAN, M D

BUFFALO N Y

THE successful endocrine treatment of menstrual disorders depends upon the diagnosis of the underlying endocrine disturbance. The signs and symptoms of the endocrine disturbance are usually present long before the appearance of the menstrual disorder. So it may be said that the most favorable time for the endocrine treatment of menstrual disorders is before the latter appear.

Underdevelopment of the uterus and menstrual disturbance result from functional impairment, disease, or removal of the ovaries, the pituitary, or the thyroid; and the conclusion is justified that normal uterine development and normal menstruation are the result of the coordinated activity of these glands.

The coordinated activity of the same glands is chiefly responsible for normal skeletal development. To the activity of the anterior lobe of the pituitary is due the growth of the flat and peaked bones and the shafts of the long bones, and the timely appearance and subsequent development of the bone nuclei for the carpal and tarsal bones and for the epiphyses are due to thyroid activity, while gonadal function brings about the union of epiphyses with shafts.

Practical use may be made of these facts in

the early diagnosis of endocrine disturbances which are known to be associated with menstrual disorders later in life.

The early diagnosis is so important, and a knowledge of it on the part of the general practitioner and the pediatrician are so essential, that I propose now to devote some attention to its discussion.

William Engelbach, in 1922, said that 70% of children whose birth weight exceeded 8 pounds, had a functionally deficient thyroid gland. Associated with this infantile obesity is delay in teething, walking, and talking.

That in infancy, as in adult life, obesity is not a constant finding in hypothyroidism is evidenced by the histories of two children.

Case 1—Infant S Female. Age 15 months. Referred by Dr Vincent Moscato, February 21, 1925. Full term baby, birth weight, 6½ pounds, breast fed for 6 months, difficult feeding case, constipated since artificial feeding began, no teeth, does not stand alone, walk, or talk, irritable, restless, and cries a great deal of the time, frequent colds.

Weight 23 pounds, pale, thin hair, very scant eyebrows with absent outer third, gracile hands with many white marks under the nails, moist eczema of hands.

Father is of eunuchoid giant type, with waist line obesity.

\*Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 12, 1925.

a serum that neutralizes 1000 skin test doses per c.c.) is a therapeutic dose. In our experience, as shown in Table IV, even three to four times this amount of antitoxin has failed to establish consistently an excess of antitoxin in the patient's blood or to exert any demonstrable influence on the course of the disease. On the other hand 3000 units as a basic therapeutic dose, is in exact agreement with the figure reached independently by Park,<sup>6</sup> who used the Dick test as a measure of whether or not sufficient antitoxin had been given in patients treated by him.

In view of the data presented above it is believed that satisfactory therapeutic results will be obtained only when an antitoxin sufficiently strong to neutralize at least 10,000 skin test doses of toxin per c.c. is employed. With antitoxin of this strength the following intramuscular dosage is recommended:

	Mild and Moderate	Severe	Extremely Severe
Children	30 to 40 c.c. (3000 to 4000 units)	40 to 60 c.c. (4000 to 6000 units)	80 c.c. (8000 units)
Adults	40 c.c. (4000 units)	60 to 80 c.c. (6000 to 8000 units)	80 to 120 c.c. (8000 to 12000 units)

#### CONCLUSIONS

- 1 Scarlatinal antitoxin in proper amount is a specific and prompt cure for uncomplicated scarlet fever.
- 2 It indirectly benefits septic complications during the acute stage of scarlet fever presumably by curing the specific toxemia.
- 3 It has not been possible to demonstrate that it possesses any therapeutic value in post-scarlatinal sepsis after the rash has faded.
- 4 To be therapeutically efficient in reasonable dosage an anti-scarlatinal serum should contain at least 12,500 minimal blanching doses of antitoxin per c.c. or be able to neutralize at least 10,000 skin test doses of toxin per c.c.
- 5 The amount of toxin required to cure scarlet fever promptly and with certainty by intramuscular injection varies from 3000 units to 12,000 units (30 to 120 c.c. of a serum which neutralizes 10,000 skin test doses of toxin per c.c.), depending upon the size of the patient and the severity of the disease.
- 6 To obtain the best therapeutic results the full amount of antitoxin required in each case should be estimated and given at once as soon as the diagnosis is made.

#### DISCUSSION

DR AUGUSTUS WADSWORTH—I appreciate the privilege of opening the discussion on Dr Blake's paper, and also welcome the opportunity to report to you the work which we have done toward preparing serum for your use.

At the May meeting of the Association of American Physicians in Atlantic City last year, Dr Blake's report of the treatment of scarlet fever with the Dochez antiscarlatinal serum was so striking and so convincing as to the therapeutic value of the serum in the early stages of the disease that cultures were secured from Dr Dochez and the immunization of horses was started during the summer. About the same time, I wrote Dr Dick for transplants of his culture, hoping to compare the action of the serums produced with these different cultures, but I was unable to secure a transplant of the Dick culture. Our experience, until very recently, has therefore been limited to a study of the Dochez strain and of strains that we have been able to obtain from various sources.

Miss Kirkbride and Miss Wheeler have already presented at the recent meeting in Washington the results of their study of scarlatinal and other strains of hemolytic streptococci. They fortunately discovered that some goats are susceptible to the action of the toxin. This fact has permitted an intensive study of the action of these toxins and of their neutralization by antitoxin, which facilitates greatly the standardization of the scarlatinal antitoxin. The evidence in regard to the action of the serum which Drs Dochez, Blake, Trask and Lynch, and also Dr Birkhaug of Baltimore, have accumulated in the last year, together with the observations of Dr Park at the Willard Parker Hospital, leaves no question as to the efficacy of the serum treatment of scarlet fever in the early stages. The fall in temperature, disappearance of the rash and marked improvement in the symptoms—in short a true crisis—suggest very strikingly that the toxemia is neutralized, as it is in the treatment of diphtheria with antitoxin.

We have gradually accumulated a supply of the serum, and from results of our tests and the reports from Dr Blake, the serum which we have prepared by the method of Dochez is equivalent in potency to his serum. The serum has been available since November, but only in limited quantities. It is now being more generally distributed, chiefly in the larger centers of population and the more important district supply stations. Physicians, however, have not used the serum very generally, and only very few reports as regards its use have as yet reached us. These simply confirm those you have already heard.

I am especially interested in Dr Blake's very lucid explanation of the mechanism of the de-

roid nucleoprotein (1%) tablets were prescribed, because of the child's appetite, which had always been poor, particularly for breakfast. This was taken for 6 weeks, with an improvement in appetite and a gain in weight of 3 lbs. She was seen again on April 20, 1925. She was of normal height, but a few pounds underweight for her age. She was pale, flat-chested and had a protuberant abdomen. The nails of her gracile hands showed many white spots and ridging. Her teeth showed separation of the upper incisors, malocclusion of upper and lower lateral incisors and canines, and notching. Thyroid deficient patients show not only late dentition, but malocclusion, notching, absence of enamel, and early loss of teeth.

Spacing of the teeth is a pituitary sign, separation of uppers and sometimes of lowers, occurs in underactivity of the anterior lobe, and separation of uppers and lowers is a result of over-activity.

This child's osseous development was advanced for her years, so she was of a pituitary-thyroid type. Because of her chief complaint, loss of appetite, thyroid was again prescribed.

*Cases 6 and 7*—Two children, a boy and a girl, of different families, but of the same age (9 yrs.) and showing the same development of the hand and foot. Both showed the presence of all the carpal bones for the age, but they were underdeveloped. The epiphysis which should be complete at this age was fast appearing and was like a dot. The girl had a poor appetite, a frequent finding in subthyroidism, and the boy was a bed-wetter, a not uncommon complaint in this condition.

The thyroid enlarges after removal of the pituitary and the pituitary hypertrophies after removal of the thyroid, and there is clinical evidence that one attempts to compensate for the other.

The next patient is cited as an example of this compensatory effort and to point out the characteristics of the juvenile type of obesity (Engelbach). The juvenile type of obesity is of the posterior pituitary type and may be associated with under or over activity of the anterior lobe.

*Case 8*—M. L. Age 10 yrs 10 mos May 1, 1925, height 50 inches (52) weight 74 lbs (58.8).

She weighed over 9 lbs at birth, was breast fed for 13 mos, first tooth at 12 months, talked at 15 mos, and walked at 18 months. She had measles, pertussis and pneumonia. Gracile hands with many white spots. There was fat distribution in the waist and shoulder girdle. (The later pituitary cases show, in addition, pelvic or hip girdle obesity. This is in contrast to the thyroid distribution which is universal with supra- and infra-clavicular fat pads and dorsal wrist padding, and to the ovarian, in which, early, there is seen trochanteric padding, and later, mammary, mons, hip and thigh obesity.) The child's mother weighs 236 lbs at the age of 33 yrs, and has given birth to two other children whose

birth weight was between 9 and 10 pounds.

The patient's general condition was noted in an examination to determine the cause of a limp, for the relief of which she came to me. This limp had been present for about a year and was due to a condition of her right hip which was painless and associated with internal rotation and limited abduction. After a conference with Dr. A. W. Thompson, the radiologist, and Dr. A. A. Gartner, the orthopedist, it was decided that Perthes' disease was the most probable diagnosis. Perthes' disease is of unknown etiology and is characterized by flattening and broadening of the epiphysis with distortion of its ossifying centre, and irregularity in outline of epiphyseal cartilage. It would be interesting to know if any other such cases have been associated with the signs and symptoms of endocrine disorder.

At puberty, the graafian follicle and corpora lutea begin to function and menstruation appears. Menstruation appears at the age of 14 (Novak). But before considering the more common types of menstrual disorder associated with an endocrine disturbance, I wish to draw your attention to two things.

*First*—The different types of hypoplastic uterus: the fetal, the infantile and the sub-pubescent.

*Second*—The typical, radiographic findings in the terminal phalanges of the hand, seen in acromegaly, which consist of tufting and mushrooming. These changes indicate that, at some time, the anterior lobe of the pituitary has been overactive. Underactivity is the inevitable result of overactivity, and a patient showing these changes may actually be suffering from an underactivity of the anterior lobe. In the presence of these signs, how distinguish between over and underactivity?

The anterior lobe of the pituitary is concerned not only with skeletal and genital development but in maintaining the tone of skeletal muscle. With the anterior lobe in a state of overactivity the patient is unusually strong and energetic, but when underactivity is present, weakness and fatigue are marked. This fatigue is present all the time and made worse by exertion, in contrast to thyroid fatigue which is worse in the morning and gets better as activity increases.

*Case 9*—M. K. First seen in 1913, at the age of 5, for enuresis. The father is tall, thin, and of eunuchoid proportion, the mother is short with the pituitary type of fat distribution.

Birth weight—7½ lbs, first tooth, 11 mos, over 1 year old when she talked and walked. Breast fed for one month.

Shortly before, Blair Bell had reported relief of this condition, in 7 children, by thyroid feeding, and this child's complaint disappeared under the influence of daily doses of ½ grain of thyroid. In 1916, she complained of fatigue, anorexia and constipation. She was always a pale child with a fatigue posture, stoop-shouldered, flat-chested with a protuberant abdomen. Again

Mother is short, thin, and has a goitre

Radiographic study showed absence of 3rd cuneiform (1 yr) and underdeveloped carpal bones

Thyroid nucleoprotein (1%), t.i.d. was begun on Feb 24, 1925

On April 4th Dr Moscato reported that by March 6th the 1st lower incisor and on the 16th, the 2nd lower incisor had appeared, and an upper tooth was visible by April 4th. By April 1st the child was walking alone. He looked better, appetite and sleeping had improved and bowels were moving regularly. On May 8th—good color, walking, 4 teeth

Case 2—Baby, 4½ years. Referred by Dr Kruse

This child required incision and drainage of a suppurative cervical adenitis. We were fearful of giving him an anesthetic because of a history of convulsive seizure occurring over a period of 14 mos., which might be due to a status thymolymphaticus. Every other day he had been having slight seizures during which there was a temporary loss of consciousness and at intervals of three weeks general convulsions. He was a premature baby, his mother having had eclampsia

Birth weight 3½ lbs., first tooth at 14 mos., walked at 18 mos. and did not talk distinctly. He has always been constipated, cathartics used frequently. Radiographic examination showed no enlarged thymic shadow, but it did show delayed skeletal development

Thyroid nucleoprotein (1%) began on March 3, 1925

Report on May 9th—much brighter, bowels move daily, looks better, has had two slight seizures in ten weeks

Father and mother were both short and thin. Mother had a goitre

The next two cases are also in boys. Their histories, as well as that of the immediately preceding one, are given because they represent conditions which may be found in either sex

Case 3—This boy, W W., at the time of his admission to my service at the Emergency Hospital on July 18, 1924, was 6 years 7 months old. He had a compound depressed fracture of the right frontal bone, a compound fracture of the middle of the right femur, a simple comminuted fracture of the left femur. The depressed fracture was elevated and both lower extremities were temporarily immobilized in a double plaster spica. Later, the plaster was removed and traction used. On August 12th an open reduction of the right femur, and 10 days later a similar operation on the left femur, was done, two kangaroo tendon sutures were used on each side, immobilization again secured by plaster. Forty-six days after open reduction of the right femur, the cast on the right side was removed and non-union was found. This boy's gastro-intestinal

activity was sluggish, and after each meal there would be a marked abdominal distention. It was considered that these symptoms might be caused by a deficient thyroid secretion. Thyroid insufficiency is given as one of the causes of non-union of fractures. Radiographic examination of the hand showed the carpal development of 5½ years. On Sept 26th, the administration of Thyroid nucleoprotein (1%) tablets, t.i.d. was begun. Fourteen days of medication showed a decided improvement in his color, an improvement in intestinal activity and a lessening of the frequency of the abdominal distention. At the end of three weeks the union of both femora was firm and at the end of four weeks it was solid.

The mother was short and thin and had no goitre

Case 4—Boy, age 6 years. Admitted to the Emergency Hospital on February 5, 1923, with extensive third degree burn of right side of chest and inner side of arm. He was seen first on May 1, 1923. He had a severe acute bronchitis and looked very ill. He had had several such attacks in the past two months and two skin graftings were unsuccessful. The burned area, on May 1st, showed a dirty, unhealthy-looking granulation tissue. The local treatment was continued as before and cod-liver oil, which he had been taking for three weeks, was continued. The only addition to the treatment was thyroid residue M.V. t.i.d. By May 28th, he sat out of bed for the first time. Not only did his general condition and appearance improve, but, on his discharge from the hospital on July 15, 1923, all but a small area in the infraclavicular region was healed. His thyroid medication was given for about 3 months in all. In March 1925, at the age of 8 years, he returned to the hospital and Dr. Gallivan did a plastic operation for a contracted scar near the shoulder. A radiographic examination showed the carpal development of a 7 year old. This showed that he not only needed thyroid in 1923, but that he still needed it.

While this patient undoubtedly had a congenital functionally deficient thyroid gland, the condition was aggravated by the burn. Jacobson has shown that the toxins formed in extensive burns have a destructive action on thyroid tissue (McCarrison).

In these young patients, thyroid and pituitary deficiency may coexist. Engelbach and McMahon say that they are associated in two forms: the pituitary-thyroid and the thyro-pituitary. In the pituitary-thyroid, the pituitary, and in the thyro-pituitary, the thyroid is primarily involved. In the pituitary-thyroid, skeletal development is more, and in thyro-pituitary, less advanced than in the pure hypothyroid case.

Case 5—J J. Female—age 7 years—June 29, 1924

She was seen on June 29, 1924, when an infection of the leg was incised and drained. Thy-

felt it necessary to continue her work because she was the main support of younger brothers and sisters. The grippe infection undid all the improvement, a result seen in hyper- and hypothyroid individuals.

Her mother was short, thin, had a large goitre which had been present for years, and showed the same type of sella and terminal phalanges as the daughter.

*Case 12*—Mrs S B Age 25 yrs—February 16, 1920

Dizziness, constipation and irregular, scanty periods began after recovery from an influenzal pneumonia in 1918, following labor. Complaint amenorrhea for four months. Thyroid medication (residue MX tid) continued for five months was followed by the reappearance of normal menses and the disappearance of her other complaints. In December, 1924, she complained of dizziness falling out of hair, and constipation, in November the period was 5 days late and scanty, and the December one was 10 days overdue. Thyroid was given with an improvement in her hair and intestinal condition, but the menstrual delay this time was due to pregnancy as the presumptive signs of pregnancy were present. On January 20th there was no improvement in fatigue. She showed an alabaster skin, longitudinal ridging of the nails with many white spots under them and marked tufting. Anterior pituitary Gr V, tid was ordered. On April 22nd, she reported that the fatigue was practically gone and she felt much better than with her first pregnancy.

The anterior lobe feeding will be continued throughout pregnancy, because the pituitary enlarges during pregnancy, doubtless as a result of an increased demand. Thyroid will be added if she again shows signs of deficiency of that organ. This type of individual should be watched closely after pregnancy, as it is after labor that their menstrual disturbances are apt to appear.

*Case 13*—Mrs H Age 28 yrs May 15, 1924 Referred by Dr Marshall Clinton

Complaints were abdominal pain and tenderness, fatigue, headache, obesity, and amenorrhea.

The pain was severe and constant and in the lower abdomen and the tenderness was marked at both ovarian points. The fatigue was constant. The headaches were of two types a constant, vertical one, and a periodic one during which she felt as though there was a tight band about the head. In 1914, her weight was 135, in 1921, 185, and at the time of examination was 246½ lbs.

Menstruation began at 13 yrs, was of the 28 day type, lasted for 3-4 days, and was accompanied with severe pain for 2 days. Irregularity began after the birth of her only child in 1919. At first, the periods were from 2 to 5 months overdue and profuse, and during this time, pregnancy was suspected once, and a curettage was done some months later for the relief of the pro-

fuse flow. For the past 3 years menstruation was scanty. In 1923 she had a scant period in February and again in June. Since then she has had no period.

At the age of 4 years she had scarlet fever complicated with nephritis, between 10-12 years, severe attacks of measles, mumps, and chicken-pox, and at the age of 22 years an attack of influenza, which incapacitated her for 5 weeks.

Physical examination showed height, 5 ft 2 inches, weight, without clothes, 246½ lbs, fine scant hair, absent outer third of eyebrows, thyroid, normal in size and consistency, fine, white transparent skin, which bruised easily, feminine type of hair distribution, hypogonad hand with many white spots under the nails, and an atrophic uterus. There was shoulder, girdle, mammary, waist, hip, thigh and leg obesity, the measurement of the thighs at the level of the great trochanter, was 51 inches. At first, ovarian feeding was given later, from July 17, 1924, to February 2, 1925, ovarian and anterior pituitary extracts. As a result of this treatment, the constant abdominal pain disappeared, but she had severe pain at intervals of 28 days and lasting for 4 days. This was accompanied by a headache which was less severe than before. The constant headache had disappeared, the fatigue was less marked, her appetite, which had been very poor, had improved, but she had had no period. On February 2, 1925, ovarian was discontinued and posterior pituitary, gr ½, was given with the anterior pituitary. Two weeks afterward at the periodic time, her pains were less severe, she had profuse nose bleeds for 4 days with general great relief. In March and April she had a normal period, flowing 4 days, and had no pain, headache or clots. On March 23rd, glytutary pills were prescribed, one after meals.

On May 11th, her weight, with clothes, was 231½ lbs, a loss of 15 lbs in about 1 year. She felt well, her period was one week overdue, she had a severe headache, of short duration, the first in months. On May 9th, ovarian extract was prescribed with whole pituitary. Her only child when seen at the age of five and a half years was backward and suffered from enurism. His carpal development was that of a child of four.

Irregularity, with scanty or profuse periods, following pregnancy invites an examination to determine the presence of signs indicating disturbance of function of the endocrine glands.

You will have noted that the children whose cases were cited showed the stigmata of thyroid or pituitary deficiency or both, and that one or both parents showed evidence of endocrine disturbance. In other words, heredity is the potent factor in the development of these dyscrasias.

The use of glandular extracts will not change the laws of heredity, but their judicious use, where indicated, will minimize the evil effects of

improvement was seen under thyroid medication. In November 1919, when 11 yrs old, she was seen after a 2 year interval. Her mother had given the thyroid at intervals and the girl felt well, had a good appetite and her bowels were regular, but her pallor was still marked. Thyroid was continued and given regularly. In May 1921 (13 yrs of age) she showed secondary sex characters, complained of fatigue and showed a moderate enlargement of the thyroid, she had lost a few pounds and had a poor appetite. Ovarian extract was added to the thyroid. Two months later she had her first period, it was normal in every respect, and the goitre had disappeared. At the beginning of her regular and persistent treatment in November 1919, she was 4 ft 9 $\frac{3}{4}$  inches tall and weighed 70 lbs. In October 1922, she was 5 ft 2 inches tall and weighed 95 $\frac{1}{2}$  lbs. On May 2, 1925, she was 5 ft. 2 inches tall and weighed 110 lbs—no increase in height, but a gain of 4 $\frac{1}{2}$  lbs in 2 $\frac{1}{2}$  years. Thyroid, in the interval, had been given by the mother for a few weeks at a time. The periods have been regular and painless since puberty. Rectal examination showed a retroverted, infantile uterus.

This patient is an example of combined pituitary and thyroid underfunctioning, and illustrates the necessity for strict supervision and frequent examinations of these types of patients, and the wisdom of determining the type of uterus, at, or shortly after puberty, even if the periods are normal. Anterior lobe extract was prescribed not only to stimulate skeletal growth but development of uterus.

That stimulation of the growth of the uterus by anterior lobe extract is not a vain hope, is shown by the next history.

*Case 10*—N A. Single, 20 yrs. Seen, May 1924.

She complained of scanty, painful periods and fatigability and anorexia. Height, 5 ft 1 inch. Wt 100 lbs. "Boyish build."

Menstruation began at 14 years, it is 2-3 weeks late, with scanty flow for 3-4 days, and accompanied by very severe pain in the right lower abdomen. The patient spends the first two days of the period in bed. Influenza in 1920, after the dysmenorrhea became worse, frequently lasting through the entire period. On rectal examination an anteverted, infantile uterus was found. Anterior pituitary feeding has brought about regularity, more profuse flow and a decrease in duration and intensity of the pain, this now lasting no more than a few hours. Her uterus when examined two weeks ago was nearly normal in size. She had been under treatment about seven months.

Four months ago, thyroid was added because of the persistence of anorexia. Appetite has improved and the thyroid will be discontinued. The period this month was 2 days early, severe pain

for 4 hours. Ovarian extract will now be added to the anterior pituitary.

*Case 11*—Miss MacG. Age 24 yrs. Referred by Dr W C Johnson. This patient was first seen on October 24, 1924. She had the classical symptoms of exophthalmic goitre, which had been present since March, 1924. She weighed 9 lbs at birth, did not know about teething, talking, and walking.

Measles at 5 yrs, typhoid at 8 yrs, and influenza for two weeks at the age of 20 yrs. She says she "catches" everything.

Menstruation began at 11 yrs, always 3-5 days late, scant flow for two days, severe backache during period. Amenorrhea since June, 1924, when she flowed one week.

She was 5 feet 3 inches tall, weighed 138 $\frac{1}{2}$  lbs and showed mammary, waist, and hip obesity. Malocclusion of upper and lower teeth, fine, thin, white (alabaster) skin which bruises easily, hypogonad hand with gracile fingers, infantile retroverted uterus. The thyroid was uniformly enlarged, there were present marked exophthalmus and a fine tremor, with a pulse of 120. Because it seemed probable, in this case, that the exophthalmic goitre was the result of an effort to compensate for the ovarian and pituitary deficiency it was decided to try the effect of endocrine therapy before recommending operation.

From November 6 to December 30, 1924, she was given ovarian nucleo-protein, one tablet t i d. She had a period 31 days after beginning medication, which lasted for 2 days. By December 30th her tremor had disappeared, the goitre was smaller, her nervousness was less marked, the pulse was 116-120, the appetite was more normal. She still tired easily, but was sleeping better. On the 30th, anterior pituitary, gr V, was added to the ovarian. An on February 5th, the condition was as on December 30th. She had another period on January 16th and 17th, which was more profuse than the one in December. Her pulse was still 120. On February 5th, anterior lobe feeding was discontinued and adrenal whole gland, in the form of adrenal nucleo-protein tablets, was added to the ovarian medication for the "checking" effect on the thyroid secretion. By March 27th, her pulse was 90, she was feeling stronger, her weight was 140 and her waist measurement had decreased 4 inches.

Ovarian and adrenal medication stopped and whole pituitary given. During the two weeks she was taking this she felt very well. On April 12th an attack of grippe began. She had not continued with her medication during her illness. She was in bed for one week and remained away from work for one week longer. When seen on May 1st, her tremor had returned, her goitre was larger and she had a pulse rate of 128.

During all the time she was taking the glandular extracts she continued at work despite repeated admonitions that rest was imperative. She

## FUNCTIONAL ABNORMALITIES OF MENSTRUATION \*

By GEORGE M. GELSER, M.D.

ROCHESTER, N. Y.

**I**N discussing the functional abnormalities of menstruation, I want to emphasize the importance of a careful detailed history of all menstrual irregularities, as well as of all pelvic symptoms. Even minute variations in the menstrual function have their significance and by proper interpretation of these significant facts, one should gain a fair conception of the diagnosis before an examination is made. In doubtful cases, when the findings on examination are not conclusive, details obtained in the history may be of much more value in reaching a diagnosis than the physical findings.

In order to understand the abnormalities of menstruation, it is necessary to know the physiology and normal process of this function.

The modern conception of the physiology of menstruation is as follows: Assuming the average menstrual interval to be twenty-eight days, the graafian follicle ruptures and the ovum is discharged between the twelfth and fourteenth day of the intermenstrual interval. After the follicle ruptures, its capsule is transformed into the yellow corpus luteum. This consists of corpus luteum cells which are a real ductless gland and which produce hormones whose function is to produce the premenstrual thickening or hyperemia of the endometrium.

If the ovum is not impregnated, it dies at the end of fourteen or fifteen days, and when the ovum dies, the corpus luteum degenerates and becomes obliterated. If the ovum becomes impregnated, the corpus luteum persists at its height until the middle of gestation, after which it diminishes until delivery of the fetus, when it disappears. The function of the corpus luteum therefore is twofold: (1) it prepares the mucous membrane for menstruation, (2) it protects the pregnancy.

Menstruation is impossible if there is no regular process of ovulation and corpus luteum production. On the other hand, there may be ovulation in the ovary without menstruation because of a poor mucous membrane, atrophy, anemia, etc.

Immediately upon the death of the ovum the corpus luteum begins to degenerate. Then the endometrium, having lost its activating force, loses its hyperemia, and the relaxation of the pressure opens the ducts of the glands which have been distended with secretion. This then pours over the surface of the mucous membrane and produces the increased vaginal secretion which many women notice before the menstrual blood appears. The secretion of the glands contains a tryptic ferment which then digests the mucous membrane and bleeding commences. The

reaction of the uterus is alkaline, which allows the ferment to act, the vaginal secretion is acid and there no digestion takes place. Menstrual blood does not coagulate because it is mixed with trypsin which prevents coagulation. If there is too much blood or too small an amount of trypsin clotting occurs, but this is always pathological and there is normally an equilibrium between the blood and trypsin.

The ovary and corpus luteum are not the only factors in preparing for menstruation. The ovary is dependent on the other ductless glands, especially the hypophysis and the thyroid. The anterior lobe of the pituitary stands in close relation to the ovary and produces an hormone which furthers the action of the ovary. If this hormone is absent, the ovary does not function properly and the frequent condition of hypoplasia of the generative organs is probably due to a deficiency of this pituitary hormone.

Under the subject of functional abnormalities of menstruation might properly be classified the menstrual disturbances associated with general constitutional diseases, as tuberculosis, chlorosis, diabetes, etc.; those associated with mental diseases, excitement, worry, sudden shock, and also those resulting from chilling or wetting of the skin, change of climate, etc. These menstrual disturbances, however, are a part of the general systemic condition, and because of the short time allotted for this paper, I will take up only the abnormalities of the menstrual function itself.

First there are the variations of the menstrual interval peculiar to certain women who habitually have regular menses of the twenty-one, twenty-five, or up to thirty-five day type. These variations from the average twenty-eight to thirty day type are normal habit for these women and are due to the different time of rupture of the graafian follicle, probably from a hypo- or hyperactivation of the hypophysis. Another rather common variation is bleeding for one or two days at the middle of the intermenstrual period, which occurs at the time of rupture of the graafian follicle and is frequently accompanied by some abdominal pain.

Some women have a variation in the menstruation itself which occurs for one or two days, ceases for one or two days and then returns. This is due to an anatomical difference in portions of the endometrial glands and secretions whereby bleeding occurs in different portions at different times and may be over in one section before it has started in the other sections.

The functional disturbances of the ovary are of two kinds, hypofunction and hyperfunction. Frequently these functional disturbances are entities in themselves.

\* Read at the annual meeting of the Medical Society of the State of New York at Syracuse May 12 1925

such heredity, and will make more nearly normal the development of these children

The infant's thyroid contains little or no iodine, and its full functional activity is not attained until months after birth, so the thyroid needs of the child must be supplied through the mother's milk. But these subthyroid mothers are unable to nurse their children, or, if they are so able, the thyroid supply is not adequate for the child's needs. Cow's milk is substituted, the thyroid content of which, according to McCarrison, differs in kind and quantity from that of mother's milk.

If a woman's thyroid, and the same is true of the pituitary, is inadequate to properly supply her needs, the added burdens of pregnancy and lactation will certainly not increase the gland's functional capacity, so treatment of such women before, during, and after pregnancy is not only indicated—it is imperative.

I have seen thyroid feeding in a lactating woman increase the amount and improve the quality of her milk and change a fretful, unhappy nursing into a happy one. The woman had a goitre which was probably aggravated by chronically infected tonsils. And I have observed the difference in development brought about by thyroid feeding in one of two children of the same subthyroid mother. Both these children have been under my observation since birth, one for nearly ten, the other for almost eight years. The first, who weighed 9¾ pounds at birth, was breast fed for three weeks and was tardy in walking, talking, and teething, the second, after the mother's condition had been recognized and thyroid extract administered before, during, and after pregnancy, had a birth weight of 8 lbs., was nursed for seven months, with a development so nearly normal as to seem precocious, when compared to that of the elder child.

In the cases after puberty, restoration of endocrine equilibrium was brought about, judging from the improvement in the menses, by ovarian, thyroid, or pituitary feeding, and some of them required all three. This may explain, in part, the contradictory reports as to the efficacy of extracts of particular organs.

There are failures from the use of each and all of these extracts. Some of these failures are doubtless the result of a polyglandular sclerosis as described by Falta, and the explanation for others may be that properly prepared extracts are not given in adequate dosage over a sufficient period.

The cases after puberty are essentially pluriglandular. Even though the obvious signs point to involvement of one organ, careful observation will usually reveal additional, and no less obvious signs, pointing to involvement of the other glands.

The signs of ovarian deficiency are, besides the menstrual ones, dizziness, occipital headache,

"nervousness," hot and cold flashes, early there is trochanteric fat padding, and, later, a mammary, mons, hip and thigh fat distribution.

With thyroid involvement a goitre may or may not be present. The goitre may be associated with other symptoms of hyperthyroidism, or more frequently, in my experience, with those of hypothyroidism. The more frequent signs and symptoms of hypothyroidism are loss of hair, scanty eyebrows, pale or sallow complexion, crowded or maloccluded teeth with early decay, dry skin, fatigue worse in morning, anorexia, and constipation. Later, the characteristic thyroid obesity is seen, universal fat distribution, with supra and infra-clavicular fat pads, and dorsal wrist padding.

The anterior pituitary deficient may be short, tall or normal in height, but whatever the height, the relation of trunk to lower extremity is usually eunuchoid, this is a small head and receding chin, or there may be a prognathous jaw, spacing of teeth—upper, lower or both, hands, in which the phalanges are disproportionately long, with white (atrophic) marks under the nails, an alabaster skin, with either female or male hair distribution, loss of libido, and fatigue. With posterior lobe involvement, shoulder, waist and hip girdle obesity are seen late.

In the past year 52 cases of menstrual disturbances were seen in which radiograms were taken of the sella and of the hand. In these cases signs of pituitary deficiency were found in association with large and small sellae. The size of the sella is no indication of the size or functional capacity of the contained pituitary. In all the cases, however, some degree of tufting in the terminal phalanges, with or without mushrooming was seen, and the more marked the symptoms and the longer their duration, the more evident were these changes. So constant a sign must have some significance. As was pointed out before, the tufting and mushrooming are considered as evidence that overactivity of the anterior pituitary was present at some time. This associated with fatigue—constant and made worse on exertion—is taken as an indication that underactivity is now present and that anterior pituitary medication is needed. If there is present shoulder, waist and hip girdle obesity, extract of whole gland is given.

The outstanding lesson to be learned from these cases is this. Glands of internal secretion are not isolated organs, but each gland is to be considered an integral part of a interrelated chain of glands. Furthermore, that they affect and are affected by the nervous system and other organs of the body. With this broad conception of the subject one's attention is less apt to be concentrated on the presence of an obvious goitre, a menstrual disturbance, or dwarfism and gigantism as to neglect the study of the patient as a whole.

sults are obtained from the injection, intravenously, of ovarian extract, either of the whole ovary or of ovarian residue, without the corpus luteum. Small doses of thyroid extract, 1/10 to 1/4 gr., and extract of anterior pituitary, 1 to 2 gr., can be combined with the ovarian extract to advantage, as they stimulate the ovarian function and further its action. Corpus luteum extract is not used for hypofunction. The corpus luteum has two different substances, in the young developing corpus luteum is a substance called lipamine which incites the premenstrual hyperemia, but the mature yellow corpus luteum has a lipid, lutein substance which checks the bleeding. Therefore, for excessive bleeding of hormonal origin, good results are obtained from the use of corpus luteum extract, especially if combined with pituitrin, 1 c.c. Corpus luteum extract, therefore, is used for bleeding of hormonal origin either during puberty, during the period of menstrual life, or at the menopause. For the symptoms of ovarian insufficiency after the menopause, extract of whole ovary gives marked relief.

By far the most striking results in the treatment of functional ovarian disturbances, have been obtained by means of the X-ray. Radiation has been most commonly used for excessive bleeding, especially around the time of the climacterium, but more recently it is being used for functional bleeding at any time of life and also as a stimulant for treatment of hypofunctional conditions. This stimulating action of the X-ray is not quite certain but is probable.

Ovarian tissue is very susceptible to the X-ray, and with it one can kill all the ovarian follicles, producing a permanent amenorrhea. With a smaller dose one may kill not all the follicles and have a temporary amenorrhea, for two to three years. If a still smaller dose is used, one can effect the development of the corpus luteum and have less intensive menses but still preserved. With a full castration dose, one also gets the climacteric symptoms, but by using only 2/3 to 3/4 the castration dose, one can get amenorrhea without the climacteric symptoms, called exovulation, where the follicle cells are destroyed but not the lutein cells.

In this connection it is interesting to note that X-ray castration usually produces more marked climacteric symptoms when effected at the time of the menopause than in younger people, while the reverse is true with operative castration. For ovarian bleeding at the time of the menopause X-ray castration is the ideal treatment, but should however, be preceded by a diagnostic curettage to eliminate the possibility of uterine malignancy. For bleedings occurring before the age of the menopause, one can radiate the ovaries with varying dosage to obtain the results desired.

For hemorrhages occurring at puberty, one can radiate the ovaries in proper dosage, without any damage to the organs. Prof. Weibel treated fourteen cases of this type in patients between the ages of thirteen and twenty years, and had

positive effect with oligomenorrhea in eleven, while in three there was no effect because treatment was not continued. He states no harm is done to the ovary in this treatment and he has seen many cases of pregnancy following it. If pregnancy occurs too short a time after treatment, there is more danger of abortion, but if it occurs after two or three years interval, pregnancy is normal and the children are normal. He also believes the same effect can be obtained by treating only one ovary. One ovary can first be treated and then if no effect is obtained, the other side can be treated. In sixty-nine cases in which he treated only one ovary, he had good effect in 87.5%, with amenorrhea in 50% and oligomenorrhea in 37.5%.

For cases of hypofunction with amenorrhea and oligomenorrhea, one may get some effect by using small stimulating radiation to the ovary, but here one risks the danger of killing the ovarian function already present. However, results have been obtained in this way and Prof. Adler told me he had had two patients with amenorrhea and sterility who had become pregnant following small stimulating radiation to the ovary. The dosage for this is 1/6 to 1/8 of the castration dose.

By far the most striking results from X-ray treatment have occurred in the so-called essential bleeding or hæmorrhagica metropathia. This bleeding is purely of ovarian origin and responds very readily to radiation. Many women have been subjected to repeated curettages without relief, and even to hysterectomy because of this bleeding, who could have been relieved by simple radiation of the ovaries.

The most recent treatment in Vienna for most of the functional disturbances of the ovary, especially in young women, is by X-raying of the hypophysis. This is used for hypoplasias, amenorrhea, and dysmenorrhea, as well as for ovarian bleedings before the age of the menopause, and also for the hot flashes and nervous symptoms of the menopause. This work is still very recent and has not been generally accepted as yet, but it has been used for two years in the Wertheim clinic with good results.

In cases of severe bleeding where rapid relief is desired, this can be obtained by X-Ray radiation of the spleen. In Doederlein's Clinic at Munich all functional bleedings are treated by spleen radiation.

In connection with X-ray treatment, I want to sound a most emphatic warning against the indiscriminate subjection of patients to radiation of the ovaries. The essential prerequisites for this is an exact diagnosis and an understanding of what is to be accomplished, for without this one is only doomed to disappointment.

In conclusion I want to emphasize again the importance and helpfulness of a full detailed history of all menstrual abnormalities, for the finer gynecological diagnoses cannot be made without a thorough understanding of the functional, as well as of the pathological lesions.

amenorrhea, and sterility on the one hand and with idiopathic bleeding in the case of hyperfunction. Commonly, however, they are associated with gross pathological lesions and the recognition in a patient's history of the finer functional disturbances of the ovary are important factors in the differential diagnosis of pelvic disease. For instance, tuberculosis of the tube and ovary are very commonly associated with hypoplasia and amenorrhea. Likewise ovarian cysts and tumors are associated with hypofunction, due to the presence of cysts in the ovary interfering with the normal development of the graafian follicles. On the other hand, uterine myomata are associated with an ovarian hyperfunction.

Hypoplasia of the generative organs is very common, being present to a certain degree in about one-fourth of all women. In addition to the anatomical hypoplasia of the organs, the characteristic features are disturbances of menstruation, sterility and dysmenorrhea. Menstruation usually starts late, at sixteen to eighteen years, and is irregular, generally at long intervals and scanty, occasionally too frequent and increased.

Dysmenorrhea is of the spasmodic type which may be due to several causes, the chief of which is that in hypoplasia, the connective tissue is relatively increased over the muscle tissue and the uterine body is hard and tense. Therefore the distention from the menstrual hyperemia produces abnormal pain. Secondly, as the ovarian function is abnormal, the uterine secretion is abnormal and clots are formed which increase the pain. Thirdly, these women generally have a higher reflex irritability and any insult to the uterus provokes greater contraction and pain than normally.

Frequently the onset of puberty is accompanied with excessive bleeding which is due to the fact that the menstrual function is not yet well established and also to the absence of corpus luteum formation.

The menopause is accompanied with a loss of the ovarian function and is characterized by many manifestations of ovarian insufficiency, not only the common nervous and circulatory symptoms, but marked atrophy of all the generative organs. The increased relaxation of the uterine ligaments and supports accounts for the backache and the onset of prolapse which occur at this time.

Another common symptom after the menopause is pruritus vulvæ, which in the majority of cases, when not a symptom of diabetes, is due to a loss of the ovarian secretion and is relieved by administration of ovarian extract.

The bladder symptoms following the menopause have also been attributed to the climacteric disturbances of the sympathetic nerve, but I am more inclined to believe that these disturbances are due rather to the tissue relaxation and senile atrophy.

During lactation there is a physiological atrophy of the uterus which lasts until the seventh

month post partum, atrophy lasting longer than this is pathological. If lactation is prolonged beyond this period, there may result a long, pathological atrophy of the uterus and ovary with absence of ovulation. This condition may persist for years and result in a precocious menopause.

The most interesting of the hyperfunctions of the ovary is the so-called essential bleeding or metropathia hæmorrhagica, which is produced by hormones from the corpus luteum or from maturing follicles of the ovary. If follicles develop too rapidly there may not be any interval and there results a constant hyperemia of the endometrium with harming of the endothelial layer of the vessels, which become stretched, torn, and bleed. The endometrium is the bleeding part but the etiology is due to hormonal hyperemia. The continuous hyperemia may provoke an endometrial hyperplasia but, this hyperplasia is not the cause of the bleeding and curettage does not effect a cure. This endometrial hyperplasia is not inflammatory, or an endometritis, but is merely an hypernutrition.

Excessive bleeding also occurs very commonly around the time of the menopause. This may be due (1) to ripening of the graafian follicles without corpus luteum formation, (2) to insufficiency of the uterine muscle, perhaps with fibrosis and commonly associated with some enlargement of one ovary. This bleeding is characterized by longer, stronger, and perhaps more frequent menstrual periods but with no intermenstrual bleeding. It is commonly stated that any increased bleeding at the time of the menopause means the presence of malignancy, but this is not strictly true for excessive menstruation at the time of the climacterium is quite common and is differentiated from malignancy by the absence of intermenstrual bleeding.

In the treatment of functional disturbances of the ovary, great advancement has been made in recent years through the use of organotherapy and the X-ray.

For hypoplasia, measures to influence the general condition are helpful, as general hygiene, exercise, iron and arsenic, sitz baths, diathermy and anything which increases the circulation in the pelvis. These patients usually improve after marriage as a result of the increased pelvic hyperemia.

Considerable improvement in hypoplasia and hypofunction of the ovary has been obtained from the injection of ovarian hormones, but there is no absolute effect, as yet, such as occurs in treating myxedema with thyroid extract. In the presence of congenital atrophy of the ovaries, one gets no effect, for these hormones only stimulate glands which are present but which are not functioning perfectly. The history usually differentiates whether there is congenital atrophy or whether some ovarian function has taken place.

For amenorrhea and hypoplasia the best re-

that we inject is very toxic and the dose large, acceleration soon gives place to fatigue, to complete exhaustion, and finally to death, if relatively large doses are repeatedly given the condition of protein cachexia, observed in experimental animals, might supervene. Proper dosage on the other hand, results in transient but well marked stimulation without clinical apparent fatigue, and if continued for a period of time the alteration of acceleration and depression or metabolic processes becomes manifest in increased weight and general well being." Further he says, "if we fix very firmly the concept that non-specific therapy is purely a method of stimulation whereby all forces of cellular and humoral resistance are for a short period of time keyed to the highest pitch and by reason thereof, stimulation of this character is useless when the cells of the body are profoundly fatigued." Where a moderate reaction is desired Peterson advises the use of milk and if less general, but some focal effect is desired, Uddgren believes that milk with a low bacterial count is to be preferred.

Peterson also calls attention to the fact that the nonspecific reaction is a "diphasic reaction—the first effect being the intensification of the disease manifestation both generally and locally, the second being a constructive phase in which there occurs a general euphoria, a diminution of disease symptoms both generally and locally, with, at times, complete restitution to the normal. Generally speaking, he says, it has been found that the more severe the first phase the greater the clinical benefit. Therapeutic results cannot be expected when the organism is no longer capable of response to stimulation. When complete fatigue has been reached no amount of stimulation will avail and the additional burden imposed by the material injected can only harm the patient."

Even with intramuscular injections of milk, it is well to keep in mind the contraindications to the injections of the more active substances. Peterson says particular care must be observed to obtain a history of hypersensitiveness on the part of the patient—serum sickness, asthma, urticaria, angioneurotic edema, or of epilepsy or other grave nervous instability. Alcoholism, pregnancy, various cardiac lesions, and diabetes, are also recognized as contraindications to the use of protein therapy, but neither old age nor infancy is so recognized by some observers.

Sensitization to repeated intramuscular injections of milk seems to be rare, as few cases are reported, although it has been used rather extensively in Europe. This is thought to be due to the fact that the milk is boiled and so differentiated. Hecht made intracutaneous injections of milk in patients injected previously with milk and also in noninjected patients. There

was no difference in the skin response, nor was he able to demonstrate milk antibodies.

Two years ago, following a conversation with Dr. George Gellhorn on milk injections in pelvic inflammatory conditions, I introduced the treatment at the Woman's Hospital and to date we have used it in 111 house cases. The milk has been used intragluteally with an initial dose of 5 c.c. and then 10 c.c. every third or fourth day. In ambulatory cases in the out-patient department intradermal milk in 1 c.c. doses is used. These cases are not analysed in this series, but there is one or two house cases with intradermal injections which compare favorably with the intramuscular method. I have used as many as twenty consecutive doses in a single case, but most often from 6 to 8 injections, from which I believe we obtain the maximum of benefit, although occasionally a few more injections seem to be necessary.

We use Grade A whole milk and sterilize it in a water bath for one hour at 60 degrees centigrade or in the autoclave at 15 pounds pressure for 15 minutes. The bottles and corks are boiled for thirty minutes and sterile precautions are used in filling the containers. The sterile milk, in its container, is kept in the ice-box until used.

The technic of injection is to prepare the skin with tincture of iodine or alcohol and to introduce a sharp hypodermic needle, about one and a half inches in length, well into the gluteal muscles. If no blood escapes from the needle or is not obtained by suction of the syringe, then we are sure that a vessel has not been entered and we shall avoid a severe protein reaction, provided the needle is not displaced later when attaching the syringe. I feel sure that in 4 per cent of my series this precaution was not taken, for in this number there was more or less respiratory embarrassment, syncope, sharp pain referred to the back, abdomen, or legs, with rather marked erythema and in one case followed by a petechial eruption. Other precautions to be observed are to shake well the container so as to mix the cream and to draw the fluid directly into the barrel of the syringe, rather than to attempt to draw it through the small caliber of the needle. Further, to prevent the local initial pain, the fluid should be introduced rather slowly. In none of this series has it been necessary to resort to the use of novocaine, as advocated by some writers.

Following the injection there is at the site of injection more or less induration with pain for a few days, but it is never as troublesome as that following mercurial intramuscular injections, and in none of my series was there an abscess formation. Within a short time there is usually an increase in the subjective pain but marked relief within twenty-four hours after the first injection—sometimes delayed until after the sec-

# PROTEIN (MILK) INJECTIONS IN GYNECOLOGICAL INFECTIONS\*

By REGINALD M. RAWLS, M.D., F.A.C.S.

(From the Clinic of the Woman's Hospital.)

NEW YORK CITY

**D**URING the last thirty years, the treatment of pelvic inflammatory disease in women has varied from a policy of immediate operation to "a watchful waiting" policy. However, in the literature of the past four or five years there have appeared, from time to time, articles advocating a return to the policy of immediate operation even in acute conditions, but I believe I voice the sentiment of most American Gynecologists in advocating a period of palliative treatment and operations only after the subsidence of the acute symptoms with no recurrence following a rather vigorous bi-manual examination. Often pelvic inflammatory disease, especially gonococcal infection, will clear up entirely under palliative treatment, but when we have a mixed infection it is too often necessary to supplement it by a mutilating operation. Any aid to palliative treatment of pelvic inflammatory disease will be welcomed by all and such a measure I offer in the intramuscular injection of sterile cow's milk. It is no cure-all but fulfills almost, if not all, of the requirements of the ideal palliative treatment—in lessening the amount of acute suffering, lessening the number of mutilating operations, and, when operation becomes necessary, giving the patient an increased immunity to withstand the shock or to make more conservative operations possible.

It is impossible, in this article, to review the history, or the general and focal reactions of protein therapy and their assumed biological origin, but to those interested I would recommend the excellent little book of William F. Peterson<sup>1</sup> entitled "Protein Therapy and Non-specific Resistance" published in 1922 by the Macmillan Company. From a review of this book we find that during and following the period of specificity in therapeutics as inaugurated by Pasteur and Koch, and through the time of von Behring, Ehrlich, and Bordet, certain clinical observations were made which were the forerunners of what is now known as non-specific resistance.

Wright mentions several such instances that came to his attention. "I confess to having shared the conviction that immunization is always strictly specific. Twenty years ago, when it was alleged before the Indian Plague Commission, that antip plague inoculation had cured eczema, gonorrhea, and other miscellaneous infections, I thought the matter undeserving of examination. I took the same view when it was reported in connection with antityphoid inoculation that it rendered the patients much less sus-

ceptible to malaria. Again, seven years ago, when applying antipneumococcus inoculation as a preventive against pneumonia in the Transvaal mines, I nourished exactly the same prejudices. But here the statistical results which were obtained in the Premier Mine demonstrated that the pneumococcus inoculation had, in addition to bringing down the mortality from pneumonia by 85%, reduced also the mortality from other diseases by 50%. From then on we had to take up into our categories the fact that inoculation produces, in addition to direct, also collateral immunization."

Peterson says "our recognition of non-specific therapy really had its inception with the papers of Renaud, Kraus, and Ichikawa. Renaud pointed out the value of heterobacteriotherapy, Kraus definitely settled this point when he reported favorable results in puerperal infection treated with colon vaccine, and with this as a basis began the treatment of scarlet fever, plague, and septicemia. Ichikawa, independently, observed that when he treated paratyphoid cases with intravenous injections of typhoid vaccine, he obtained equally as good results as when it was used in typhoid cases."

From heterobacteriotherapy it was but a logical step to attempt intravenous injections of bacterial components and bacterial split products, then of protein split products of non-bacterial origin, and finally to the realization that any substance which was capable of inducing the shock reaction on the part of the patient would result in the same therapeutic change. Soon a number of agents were used and in 1916 Schmidt and Saxl introduced intramuscular injections of milk to induce a protein reaction, i.e. the typical rise in temperature observed following the injection of other agents.

There are many theories and much research available to explain the protein reaction but, quoting Gellhorn<sup>2</sup> who was the first to call attention, in this country, to the value of milk injections in gynecological diseases, "Protein substances, introduced 'pararenterally' that is, by subcutaneous, intramuscular, or intravenous injection, have the faculty of stimulating the cells to greater activity—of 'activating the protoplasm'. All cells of the body feel this rejuvenating influence but none more so than those cells which have been weakened or paralyzed by infection."

Quoting Peterson, "Protein therapy offers a potent, perhaps the most potent, method that we have at our command of altering the current of cellular activity in two diametrically opposite directions—acceleration of function and depression of function. If the agent

\* Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse May 13 1925

strange as it may seem, I have not done a posterior colpotomy for pelvic inflammatory disease during the time covered by this series. It has so happened that no cases presented themselves with a bulging cul-de-sac but all were of the class which formerly were treated by a waiting policy until there was function; by the use of intramuscular injection of milk these cases have cleared up with surprising promptness.

In the series of 78 cases observed from 4 to 21 months there were four cases of subsequent pregnancy—one has been delivered, one 6 months, another 7 months and the last 3 months pregnant. Three of these four cases were given milk injections for infectious post abortive or post puerperal and therefore mixed infections which usually respond unsatisfactorily to palliative treatment. Two had operative measures also but after their acute symptoms had been re-

lieved by the milk injections and thus made possible conservative work.

## THE PROVISIONS FOR TEMPORARY CARE OF THE INSANE PENDING COMMITMENT IN NEW YORK STATE

By FRANK KIERNAN

Field Secretary of the State Mental Hygiene Committee.

THE question of what happens to insane patients or supposedly insane patients between the time they are taken into custody and the time they are placed in the State hospitals or discharged as not insane has long disturbed the State Hospital Commission. It became possible early this year for the State Mental Hygiene Committee to respond to the invitation of Dr. C. Floyd Haviland, Chairman of the State Hospital Commission, to make an investigation of the temporary care conditions at least in part of the State and endeavor to secure an improvement in those conditions where such improvement seemed imperative and feasible.

In Schenectady, where in the previous fiscal year, there were thirty-six cases who needed temporary care, they had been placed in quarters wholly unsuited for such patients and under supervision that was most undesirable. We have been able in Schenectady to carry the matter to the point where it is now practically assured that this summer there will be provided at the new City Hospital adequate quarters with, of course, the proper medical and nursing supervision.

In Canandaigua which includes a considerable part of Ontario County, we are in the way of effecting an arrangement whereby quarters for these cases will be provided at the Thompson Memorial Hospital.

In Glens Falls where hitherto these patients have always been kept in the city lock-up, they

are now to be cared for in a separate room in the City Hall with trained supervision by persons obtained through the Glens Falls Health Center.

In Auburn, we expect to have rooms provided in the new Auburn City Hospital where the patients will be under the supervision of a psychiatrist and receive the ministrations of the nursing service of the hospital staff.

These are typical of the arrangements that we have been able to make to date. We desire to take this occasion to state in the presence of the Health Commissioner that the Health Officers everywhere we have visited have given us 100% cooperation and support. The same is true of the members and secretaries of the local tuberculosis committees.

The law places upon the Health Officers the distinct obligation of providing "for the proper care treatment and nursing of such person pending the determination of his mental condition." This law seemed to have been predicated upon the assumption that the Health Officer is a conjurer who could produce such facilities by the waving a wand over a silk hat. This, of course is entirely out of the question. The Health Officer can provide only such facilities as are available in his locality. Our usefulness has consisted in assisting the Health Officers to convince the local Boards of Health, citizens and hospital authorities that this type of patient is equally deserving of proper care and treatment as any other sick person, and in this we think we can say that we have been successful.

\*Read at the Annual Meeting of the Medical Society of the State of New York at Syracuse, May 13 1925

ond injection The sense of well being experienced by these cases is remarkable, especially as previously it was necessary to use repeated doses of codeine or even morphine in addition to all other methods of palliative treatment

This fact is so constant in adnexal inflammation that my associate, Dr William T. Kennedy, suggested its use as a differential sign in suspected ectopic gestation. The series so far is too small to draw definite conclusions, but in 3 out of 4 cases the failure of the injection to relieve pain was found to be due to ectopic gestation. In these few cases there was an early relief of pain but with a recurrence rather than a cessation as in salpingitis

In the early injections there is usually a rise in temperature within 6 or 8 hours, from 2 to 4 degrees or more, above the usual afternoon rise, with a return in twenty-four hours to the pre-injection level. This rise in temperature is accompanied by a corresponding rise in the pulse rate. This may continue in some cases throughout the time of treatment but usually there is no reaction after the third to sixth injection

Accompanying this reaction there is an increase in the leucocytes from 1 to 10 thousand above the existing white count, or in the earlier injections there may be a leucopenia but usually with an increase of the polymorphonuclear cells. In some cases this reaction may be delayed for 48 hours, but usually it is earlier and will have disappeared by this time

In 10 per cent of my series there was a chilly sensation or a definite chill lasting as long as 10, 20, or 30 minutes, but usually not as severe as that following typhoid vaccine injections. In an additional 9 per cent notes were made of a rather high temperature with sweating, headache, restlessness, nausea and even vomiting

When we compare the early or immediate results in 96 cases with the late or end results in 78 cases under observation from four to twenty-four months, we find them practically identical (Table I). Therefore I feel

TABLE I—Results

<i>Immediate (96 cases)</i> (On discharge from hospital) ( or end of one month )		<i>End Results (78 cases)</i> (Cases observed 4 to 21 mos )	
Recovery	(37) — 38.5%	(30)	38.5%
Improvement	(52) — 54.0%	(42)	53.9%
No Improvement	(7) — 7.5%	(6)	7.6%

that my figures are conservative and compare favorably with, although not as good as Bittman's<sup>3</sup> who reports his results of milk injections in 573 cases of pelvic inflammatory disease as

Recovery	76 %
Improvement	20 %
No Improvement	4.0%

In order to be reasonably sure of our diag-

nosis and to rule out the cases with temporary pelvic congestion or hyperemia, I have arranged in table II the results in 52 cases with masses estimated in size from 3 to 12 cm

TABLE II—Results

<i>Immediate (52 cases)</i> (Masses 3 to 12 cm)		<i>Immediate (96 cases)</i> (all cases)	
Recovery	(16) — 30.8%	(37)	38.5%
Improvement	(34) — 65.4%	(52)	54.0%
No Improvement	(2) — 3.8%	(7)	7.5%

In a tabulation (Table III) of the degree of inflammation present in the 78 patients under observation from four to twenty-one months, we may be surprised at first glance to find the results of treatment in the acute and chronic are better than in the subacute conditions. This can be explained by the fact that unquestionably there were listed many cases under chronic that were really an acute exacerbation of an old pathological condition or this old condition made the patient more susceptible to a fresh infection which, from the history of the patient, was classified as chronic

TABLE III—(Degree of Inflammation in 78 cases observed for 4 to 21 months)

<i>Acute—34</i>		
Recovery	(14) — 41.0%	
Improvement	(20) — 58.8%	
No Improvement	(0) — 0.0%	
<i>Sub-acute—29</i>		
Recovery	(10) — 34.5%	
Improvement	(14) — 48.0%	
No Improvement	(5) — 17.0%	
<i>Chronic—15</i>		
Recovery	(6) — 40.0%	
Improvement	(8) — 53.3%	
No Improvement	(1) — 6.6%	

In Table IV we have compared the cases as to subsequent operations and their results

TABLE IV —

	<i>Immediate (96 cases)</i> (On discharge from hospital)	<i>End Results</i> (78 cases) 4 to 21 months
No Operation Required	(75)—78.2%	(37)—71.1%
Operation req'd or advised	(21)—21.8%	(15)—28.9%
Total Operations	(17)	(10)
*Hysterectomy		(3)—30.0%
Conservative Operations		(7)—70.0%

\* (One of the three hysterectomies was done because of a fibroid uterus)

In only three cases in this series were positive gonococcal smears reported and I feel that had the cases been seen earlier in their infections our end results would have been even more encouraging. Milk injections are of especial value in acute salpingitis, pelvic peritonitis, and the so-called "frozen" or "plaster of Paris" pelvis, and

## WHAT IS MEDICAL NEWS

Is what doctors talk about news? An excellent test is supplied by the listener. When a group of doctors get together and all try to talk at once, there is no listener, and this fact may prove that what the talker says is mere talk and has little news value.

Many a talker deludes himself and thinks he has made a great impression when the hearers about him are responsive, and try to tell him their own experience. But he may merely have touched the spring which loosens the torrent of the listeners' own talk,—and they may have got nothing at all from the speaker. If a listener is anxious to describe a case or tell a story, he is not receptive to new ideas, and the talker's speech is futile.

Real evidence of the value of a talk is attentive silence on the part of the listeners who are eager to catch every word of the speaker. Let some one relate a bit of real news, or tell about an illuminating case of sickness, then all the crowd will listen intently. The news value of talk can be judged by the degree of silent interest shown by the listeners who lean forward to catch every word.

A talker always implies a listener. If the talker speaks of real news, he will always have receptive listeners. The medical editor or reporter wishes to catch some of the ideas that are wasted in aimless talk and fix the more valuable ones in the Journal.

Neither talk nor news is of value unless it penetrates into the brains of the hearers or readers. How do the members of the Medical Society of the State of New York read their Journal? An expression that is often heard is "I look through the Journal and read what interests me." It is the object of the Editors to make all the contents of interest to all the members.

Do all the members know how to read the Journal to the best advantage?

A professor in the University of Wisconsin School of Journalism is planning a course on how to read a newspaper. A course is needed on how to read the New York State Journal of Medicine. The Journal consists of two parts, scientific articles, and reports of activities of the State Society and the county societies. These activities are as important as the scientific articles, and any one who reads them with reasonable care will learn of the immense amount of work which the officers and committees of the societies are doing not only for the advancement of public health and civic medicine, but also for the great benefit of the individual doctor. News of the activities of the State Medical Society is the great justification for the existence of the Journal. Members frequently write for information which is plainly stated in the recent issues of the Journal. A course on how to read the Journal could be summed up in the simple injunction to read it, and thereby get the full return for the member's money that is spent in producing the Journal.

It might be a good idea for a county society to devote the program of one of the meetings to the subject of how to read the Journal. Make it an experience meeting. Take the four latest issues of the Journal and let each member present tell what he has read. Possibly the leader would conduct a quiz on the contents of the Journal. The editors might even prepare and publish a series of questions on the contents of the Journal after the manner of the syllabi and questions which sometimes appear in the literary journals.

To suggest a course for readers might be considered as mere talk, but if it were adopted the members would learn how interesting and instructive medical society news can be, and the editors would catch a glimpse of the inner opinions of the readers.

---

## DESTRUCTIVE CRITICISM

When a physician eminent in his profession says that doctors are not taking full advantage of the opportunities offered to them by modern medical research, the announcement is proclaimed in the public press and is often interpreted as a condemnation of the medical profession. New medical discoveries are broadcasted from dozens of stations, and in a score or more of specialties the general practitioners can receive from one station at a time and for only a brief period. His practice covers all the specialties, and he never knows what sort of information he will need to use next. One doctor listens in at a lecture or medical journal, and if he gets nothing that he

can put to immediate use, he is not likely to tune in on other broadcasting stations.

The broadcaster in the research station reacts largely according to his temperament. He is manager of an institution that produces medical discoveries. His success depends on salesmanship quite as much as discovery. His discoveries must be delivered to the doctors and put to general use before they can be of benefit to mankind.

The psychology of medical salesmanship may be illustrated by the old story of the Turkish Sultan who consulted his two soothsayers. The first one said "All your friends will die before you," and was headed for his doleful predic-

## CHRISTMAS

I saw a doctor wearing a trown,  
With his eyebrows up and his mouth turned  
down  
"How are folks this Christmas?" I greeted him  
"Distressingly healthy," he answered grim,  
"A few old chronics are all I see,  
"If no one gets sick or goes on a spree  
"A poor-house turkey 'twill be for me."  
And a cloud came over the sun

I saw another doctor that day,  
With a jolly round face and a breezy way  
"How are the sick folks doing?" said I  
"Delightfully hearty," he made reply  
"I sell them health and strength through the year  
'So they may enjoy their holiday cheer,  
"For Christmas is never a time to feel queer."  
And the sun shone warm and bright

# MEDICAL PROGRESS

**The Nature of Cancer, and Treatment of Malignant Growths by Lead**—IV Blair Bell (*Lancet*, November 14, 1925, ccix, 5333), in an address before the Academy of Medicine, Toronto, on November 10, described investigations carried out by a group of observers at the University of Liverpool, which are confirmatory of his hypothesis that cancer is a specific process, though not perhaps due to a specific cause. According to this theory, malignant disease in the human subject is a biological atavism. There is a time in the development of the ovum when somatic cell correlation and differentiation can hardly be said to exist, except potentially. At that early stage the trophoblast, of which the ovum is largely composed, is engaged in a struggle for existence, unless it can eat its way into the maternal tissues, the whole ovum will perish. The zygote possesses, therefore, the power of developing into cells of two types, the undifferentiated nutritive cells and the differentiated somatic cells. Normally the area in which the fetus is to develop grows rapidly, and *pari passu* the activities of the trophoblast, so far as plastic and invasive properties are concerned, are gradually arrested. Thus it appears that, when the elusive factor in somatic cell correlation becomes operative and ensures normal and differentiated development in the fetus, the growth of undifferentiated, "malignant," epithelium of the chorion is stayed. It is with the nature of this controlling factor that investigation is concerned. In view of the method of implantation of the ovum in the human subject, and of the origin of chorio-epithelioma, it seems reasonable to suppose that cells of somatic tissues, formerly normal may, through senility, injury, infection, or any of the other inciting and predisposing factors of cancer, slowly lose their power of obtaining or utilizing nutriment, and, as the process of starvation is a slow one, gradually adjust themselves to the altered and altering conditions by reverting to an earlier, undifferentiated, chorionic, nutriment-seeking type. It is possible that every cell in the body has this potentiality for atavistic reversion and once started on the perverted course, there is no reason why the de-differentiated somatic cells should be arrested, for like those of chorio-epithelioma, they are free from differentiated somatic control. In the search for confirmation of this hypothesis, a comparison was made between the chemical constitution of different tissues in regard to factors concerned in the growth processes. This study showed that chorionic epithelium and malignant cells have a water and phosphate value and a phosphate-cholesterol

ratio far in excess of that of normal tissues and innocent neoplasms. It has also been shown that permeability of the cell membrane is associated with a high phosphate value and a high phosphate-cholesterol ratio. Further, a high water content is actual evidence of permeability, and permeability is favorable to rapid growth. These are the essential features of malignant neoplasia and they are most noticeable in connection with chorionic villi.

In a search for a substance that will arrest or have a specific lethal action on cells which possess the chemical constitution associated with malignancy, the effect of various metals—beryllium, zinc, thallium, copper, thorium, lead—was studied. It was found that lead only is specifically active in regard to the chorionic epithelium, to the cells of cancerous growth, to normal embryonic growth, and to mature cells rich in phosphatides. Intravenous injections of lead have been administered in cases of human cancer. In two illustrative cases cited (carcinoma of the breast and widely disseminated abdominal sarcoma) apparently permanent cures were effected. On the other hand, in a case of sarcoma of the stomach treated by intravenous injections of lead the patient died with acute peritoneal symptoms and necropsy showed that the lead had caused total liquefaction of the stomach. In a case of rapidly growing post-cystoid carcinoma lead injections caused acute necrosis of the entire tumor, and the patient died from suffocation. The result in these instances may be confirmatory of the specific action of lead on malignant neoplasms, but it also hoists a danger signal and warns against the indiscriminate use of so potent a remedy. Blair Bell promises to publish his results in a series of cases, in an early issue of the *Lancet*.

**Periarterial Sympathectomy**—Ira Cohen (*Annals of Surgery*, November, 1925, lxxii, 5) reports 11 cases in which periarterial sympathectomy was performed for ulcer of the leg, gangrene of the toes, and thromboangitis. The operation consisted in the removal of the adventitia of the femoral artery, the site chosen being in Scarpa's triangle just below the division of the common into the superficial and deep femoral arteries. The superficial femoral artery is exposed and raised from its bed for a distance of 5 to 8 centimeters. With a fine scalpel an incision is made through the adventitia along the exposed vessel. The edge of the adventitia is picked up with fine forceps and freed by blunt dissection with a thyroid separator or small cranial elevator. When it has been freed for about half a centi-

tion The other one said "You will outlive all your friends," and was honored for his optimistic way of stating exactly the same prophecy

If the medical research worker and teacher is of a pessimistic temperament, he may say "We are turning out an abundance of new discoveries, but the doctors are not using them They are neglecting their opportunities and their patients continue to suffer from the lack of therapeutic measures which are available to those who will seek for them" This line of reasoning supplies the enemies of the medical profession with abundant ammunition for discrediting the doctors

On the other hand if the medical teacher has an optimistic temperament, he may say to the doctors, "Step up and see our new discovery Keep yourself up-to-date, and give your patients the benefit of the results of the latest medical research" This is the successful method of the committee on Public Health and Medical Education of the Medical Society of the State of New York It does not lend itself to propaganda against physicians, but it focuses one's attention on medical progress

Now let us consider the psychology of the

rivals of the physicians The cultists, too, are in the producing business, although the output is small, but their sales organizations are widespread and efficient Their salesmen say

"We cure where doctors fail Dr Blank, Professor of Medicine in the Peepul's University, says that doctors are not making use of medical discoveries Why not? Because they have lost confidence in their leaders, who give out only the information that suits them We have a medical discovery that is endorsed by Dr Blank who used it successfully on Miss Catch, the famous actress, and we will distribute it directly to you, so that you will not need to go to the doctors who are prejudiced against modern medical discoveries"

These salesmen have no difficulty in finding statements of prominent physicians in support of their insinuations of the failure of doctors It is good psychology to make your rival convict himself out of his own mouth It is good judgment for physicians to avoid expressions which may be quoted against the medical profession

Destructive medical criticism belongs only in one half of a compound or complex sentence whose other half balances the criticism with a constructive suggestion

---

### "TEACHING HOSPITALS"

One of the most striking forms of medical progress during the last five years has been the development of hospitals as centers for medical teaching This has come about largely through the adoption of monthly staff meetings by practically every hospital, both urban and rural The benefits of staff meetings have long been known, but physicians were individualistic, and many held to the old idea of private ownership of every case of sickness "No one shall tell me how to treat my cases in a hospital," was what many a doctor told his colleagues

The stimulus to lay aside one's prejudices and join with his colleagues in the free discussion of cases came from the American College of Surgeons when it began to publish its lists of approved hospitals To have his hospital approved was the ambition of every member of every staff

Staff meetings have long been familiar to those who practice in the hospitals of large cities, but they were novelties to the staffs in small cities and rural places, and their excellent effects were at once apparent It meant a revolution of thought when an individualistic doctor wrote histories of his cases and placed them on file where all his colleagues could see them It meant still more for him to be asked why his patient died and why he did not adopt a particular

method of treatment When a doctor expects to be asked embarrassing questions that reveal his ignorance, he prepares himself for the ordeal, and that means that he must study every case, for he knows not what complication may develop

Staff meetings have the praiseworthy characteristics of being real clinical meetings, in which every member must inevitably take part if he is at all active in the hospital A doctor may evade his duty in his county medical society, and take refuge behind the plea that he cannot write a paper or get up and make a speech, but in his hospital he is compelled to write history papers, and to make speeches justifying his diagnosis and treatments, and lo! he can do both as well as any one else

The staff meetings in many places are group meetings of county medical societies Some devote a whole evening to their meetings, and a few hospitals find it profitable to provide a supper for the staff

One of the most gratifying things about the staff meetings is that they are the spontaneous response of almost the entire body of physicians to an ideal simply stated by a group of doctors who had an outlook and a vision

**The Nature of Cancer, and Treatment of Malignant Growths by Lead**—W Blair Bell (*Lancet*, November 14, 1925, ccix, 5333), in an address before the Academy of Medicine, Toronto, on November 10, described investigations carried out by a group of observers at the University of Liverpool, which are confirmatory of his hypothesis that cancer is a specific process, though not perhaps due to a specific cause. According to this theory, malignant disease in the human subject is a biological atavism. There is a time in the development of the ovum when somatic cell correlation and differentiation can hardly be said to exist, except potentially. At that early stage the trophoblast, of which the ovum is largely composed, is engaged in a struggle for existence, unless it can eat its way into the maternal tissues, the whole ovum will perish. The zygote possesses, therefore, the power of developing into cells of two types, the undifferentiated nutritive cells and the differentiated somatic cells. Normally the area in which the fetus is to develop grows rapidly, and *pari passu* the activities of the trophoblast, so far as plastic and invasive properties are concerned, are gradually arrested. Thus it appears that when the elusive factor in somatic cell correlation becomes operative and ensures normal and differentiated development in the fetus, the growth of undifferentiated, "malignant," epithelium of the chorion is stayed. It is with the nature of this controlling factor that investigation is concerned. In view of the method of implantation of the ovum in the human subject, and of the origin of chorio-epithelioma, it seems reasonable to suppose that cells of somatic tissues, formerly normal may, through senility, injury, infection, or any of the other inciting and predisposing factors of cancer, slowly lose their power of obtaining or utilizing nutriment, and, as the process of starvation is a slow one, gradually adjust themselves to the altered and altering conditions by reverting to an earlier, undifferentiated, chorionic, nutriment-seeking type. It is possible that every cell in the body has this potentiality for atavistic reversion and once started on the perverted course, there is no reason why the de-differentiated somatic cells should be arrested, for like those of chorion epithelioma, they are free from differentiated somatic control. In the search for confirmation of this hypothesis, a comparison was made between the chemical constitution of different tissues in regard to factors concerned in the growth processes. This study showed that chorionic epithelium and malignant cells have a water and phosphatide value and a phosphatide-cholesterol

ratio far in excess of that of normal tissues and innocent neoplasms. It has also been shown that permeability of the cell membrane is associated with a high phosphatide value and a high phosphatide-cholesterol ratio. Further, a high water content is actual evidence of permeability, and permeability is favorable to rapid growth. These are the essential features of malignant neoplasia and they are most noticeable in connection with chorionic villi.

In a search for a substance that will arrest or have a specific lethal action on cells which possess the chemical constitution associated with malignancy the effect of various metals—beryllium, zinc, thallium, copper, thorium, lead—was studied. It was found that lead only is specifically active in regard to the chorionic epithelium, to the cells of cancerous growth, to normal embryonic growth, and to mature cells rich in phosphatides. Intravenous injections of lead have been administered in cases of human cancer. In two illustrative cases cited (carcinoma of the breast and widely disseminated abdominal sarcoma) apparently permanent cures were effected. On the other hand, in a case of sarcoma of the stomach treated by intravenous injections of lead the patient died with acute peritoneal symptoms and necropsy showed that the lead had caused total liquefaction of the stomach. In a case of rapidly growing post-cricoid carcinoma lead injections caused acute necrosis of the entire tumor, and the patient died from suffocation. The result in these instances may be confirmatory of the specific action of lead on malignant neoplasms, but it also hoists a danger signal and warns against the indiscriminate use of so potent a remedy. Blair Bell promises to publish his results, in a series of cases, in an early issue of the *Lancet*.

**Periarterial Sympathectomy**—Ira Cohen (*Annals of Surgery*, November, 1925, lxxxii, 5) reports 11 cases in which periarterial sympathectomy was performed for ulcer of the leg, gangrene of the toes, and thromboangitis. The operation consisted in the removal of the adventitia of the femoral artery, the site chosen being in Scarpa's triangle just below the division of the common into the superficial and deep femoral arteries. The superficial femoral artery is exposed and raised from its bed for a distance of 5 to 8 centimeters. With a fine scalpel an incision is made through the adventitia along the exposed vessel. The edge of the adventitia is picked up with fine forceps and freed by blunt dissection with a thyroid separator or small cranial elevator. When it has been freed for about half a centi-

meter along one side, the adventitia may be grasped with mosquito hemostats placed at intervals. Gentle traction on these clamps while using the separator will cause the vessel to rotate while the adventitia is thus peeled off until the thin fibrous coat is entirely free from the vessel and may be cut away. After this has been done the vessel is allowed to drop back into its bed and the soft parts are sutured. The operation is followed by immediate changes in the limb, contraction of the exposed vessel, subjective and objective coldness of the extremity, and diminution of the peripheral pulse. These changes last several hours and are followed by signs of dilatation of the peripheral vessels with subjective and objective increase in temperature and elevation of the arterial pulse pressure. These latter phenomena last five or six days or longer. Of the total 11 cases, 7 were of arteriosclerotic origin, 2 were thromboangitic, 1 was a case of trophic ulcer, and 1 was an ulcer complicating mild diabetes. Three patients were completely relieved of pain, 2 were slightly improved, and in 6 no benefit could be seen from the operation. The best results were obtained in patients with pain due to arteriosclerotic disease of the vessels of the legs. Priarterial sympathectomy causes definite changes in the peripheral circulation. The explanation of its action is not clear, and the indications for its use are not sharply defined. Success and failure were met with in seemingly similar cases.

To René Leriche belongs the credit of introducing this operation, an early if not the first case of which was reported by him in *La Presse Médicale* of 1920. The arterial decortication was done for the cure of an intractable ulcer in an amputation stump and was eminently successful. In a later communication (*Annals of Surgery*, October, 1921), he reported a number of successful sympathectomies for the relief of causalgia, Raynaud's disease, and various trophic ulcers. A. E. Halstead has reported a case diagnosed as one of endarteritis obliterans cured by Leriche's operation (*Journal Am Med Association*, January 20, 1923, lxxx, 3). Handley suggests periarterial injection of alcohol as an alternative to this operation (*Lancet*, July 15, 1922, ccii, p 173) and reports a case of incipient gangrene cured by his method.

**A New Method of Approach for the Removal of Deep-Seated Brain Tumors**—Walter E. Dandy (*Annals of Surgery*, October, 1925, lxxii, 4) presents a method by which tumors (principally ependymal tumors) situated within the brain substance can be exposed and ablated. The procedure involves resection of the so-called silent parts, even, if need be, lobes of the brain. A case is described of a dural epithelioma (a benign encapsulated tumor) arising from the cover of the cribriform plate, and occupying both sides of the cranial

chamber to an equal degree. The tumor was completely removed after a preliminary resection of the left frontal lobe. No loss of function of any kind followed the operation. Resection of a silent cerebral lobe is advocated, in part or whole, as a method for the removal of certain intracranial tumors known to be benign, and which are situated at such a depth as to be in large part or wholly hidden from view. For such tumors situated on the right side of the middle cranial fossa, preliminary resection of the temporal or occipital lobes would be justifiable, though, of course, contralateral homonymous hemianopsia would result. Section of the left occipital lobe posterior to the supramarginal and supra-angular gyri apparently leaves no stigmata other than a right homonymous hemianopsia. The inclusion of these sensory speech areas could hardly ever be justifiable.

The intracranial approach which Dandy describes is designed so as to avoid leaving scar on the forehead in front of the hair line. In general way it may be said that two small more or less U-shaped adjoining skin flaps, are used instead of a single large one, a middle limb serving both as the back of the anterior flap and the front of the posterior flap. The base of the anterior flap is directed toward the orbit, the base of the posterior downward toward the zygoma. The principle involved in the use of these two flaps can be variously modified. Dandy has been using this method of approach in practically every case of cerebral tumor or craniotomy for several years.

**The Value of the Leucocyte Count as an Aid to Diagnosis in Ectopic Gestation**—Lilian K. P. Farrar (*Surgery, Gynecology and Obstetrics*, November, 1925, xli, 5) has made observations on the leucocyte count in 150 cases of ectopic gestation, which she summarizes thus: (1) In ectopic gestation the leucocyte count fluctuates according to the amount of fresh blood being thrown into the peritoneal cavity and the rate of absorption. (2) The leucocyte count tends to drop quickly to normal as the blood in the peritoneal cavity is absorbed or walled in, 48 per cent of the 150 cases of ectopic gestation showed a normal leucocyte count before operation was performed. (3) The leucocyte count was normal in 29 cases of unruptured tubal pregnancy in which there was no free blood, and in 43 cases of ruptured pregnancy in which the blood was walled in. (4) The leucocyte count was an index in 150 cases to the amount of fresh blood in the peritoneal cavity and the polymorphonuclear leucocyte count was increased markedly only in cases having fresh blood in the pelvis, and increased in direct proportion to the amount of recent blood found at the time of operation. (5) The fluctuating leucocyte count, together with

the moderate elevation of temperature, differentiates ectopic gestation from a purulent salpingitis with its more uniformly high leucocyte count and fluctuating temperature (6) In cases of rupture of tubal pregnancy the steadily rising leucocyte count indicates active bleeding before the fall in the number of red cells or hemoglobin gives warning of the condition (7) The leucocyte count to be of diagnostic value must be taken at least daily, in critical cases even hourly, and used in conjunction with the history and clinical findings in the case

**Biologic Testing of Ovarian Preparations**—Zondek and Bernhardt of the Charité Hospital, Berlin, refer to the disadvantages inherent in ovarian substance in contrast with the thyroid, adrenal and pancreatic secretions, all of which contain active hormones which permit of a biological standardization It is evident that somehow a hormone must be present to explain the results of ovarian grafting We know beyond doubt that at least one dynamic action can be assigned to ovarian substance, for when castration has lowered the oxygen consumption of the woman by about 15 per cent, ovarian substance will sometimes make this deficit good again We may therefore assume that there is a hormone-like substance in the ovary and that its function is to stimulate oxidation A clinical case is reported to show that ovarian substance can cause the return of normal oxidation, although to demonstrate this truth it was necessary to supervise the metabolism of a castrated woman for two years or more Before using the home made preparation several marketed preparations were tested and found quite inert Modes of preparation and handling may, therefore, be at fault The authors are at present endeavoring to determine the identity of the hormone and isolate it—*Klinische Wochenschrift*, October 15, 1925

**Exanthema Subitum**—Seen originally in St Louis by Zahorsky and described by him under the name of roseola infantilis, in 1910, this affection was recognized later in Ann Arbor, New York, Cleveland, Houston and Detroit The first European cases were identified in Berne in 1919, and quite recently cases have been studied in Italy So far as known the affection has never been seen in Great Britain, France, or Germany Von Bokay of Budapest, who has seen 11 cases (*Deutscher med Wochenschrift*, Oct 11, 1925), regards exanthema subitum as an autonomous affection His own, like the cases seen by others, are remarkably true to type. The fever sets in suddenly in the midst of health and the patients remain relatively well despite the four days of fever which may reach 104°, and which usually ends on the fourth day by crisis Relapses may occur of the same length as the first attack. The

rash is of the measles type and always appears on the trunk, in certain cases also involving the head and extremities Authors have noted congestion of the buccal mucosa and pharyngitis The younger children seem more predisposed and while cases occur in massed incidence, contagiousness is feeble if present at all The affection is of no great clinical significance, but might of course mask some more serious condition Von Bokay says nothing of any causal factors and mentions no microorganisms The name bestowed on the disease was given in recognition of the suddenness with which the rash appears

**Respiratory Catarrh in Children**—The frequency of catarrhal troubles in the newborn is a matter of common observation, nevertheless one will read with surprise that one-half of all infants from three to six weeks of age suffer, in England at least, from nasal or bronchial colds This is the statement made by Richard C. Clarke (*Lancet*, October 24, 1925, ccix, 5330), who found in a study of his last 1,000 case-sheets that 499 young infants were already affected, and on questioning the mothers the usual answer was "Yes, 'e was born with it" These early infections tend to become chronic and are undoubtedly the cause of inadequate suckling, due to nasal obstruction, of the disease known as "tonsils and adenoids," and of chronic sinus troubles Of over 400 babies under four weeks old, who had nasal catarrh, the writer found that every one had signs of bronchial catarrh Once a child is bronchitic, every fresh cold causes exacerbation of the bronchial signs and symptoms The result is the bronchitic schoolchild and later the bronchitic adult The bronchitic child is severely handicapped, for attacks of bronchopneumonia occur with frequency, while measles, whooping-cough, and even the administration of an anesthetic present added risks in such a case The question of pathogenesis is bound up with the factors which control the spread of infectious disease In order to prevent this condition, the morbid dose of catarrhal organisms on the respiratory mucous membranes must be postponed as long as possible There can be no fear of the child missing the submorbid or immunizing dose. In order to avoid the morbid dose the mother should carry out antepartum nasal hygiene, and after delivery if she has acute catarrh, she should wear a folded handkerchief over the mouth and nose when attending the baby The same precaution should be adopted by nurses or other attendants To avoid the other main avenue of infection, the germ-laden atmosphere, is not difficult in the uncrowded house, but if the infant belongs to the overcrowded class it should either be kept out of doors or in a draught The latter point is insisted upon by the author who implies that children do not suffer discomfort from a moderate degree of cold

meter along one side, the adventitia may be grasped with mosquito hemostats placed at intervals. Gentle traction on these clamps while using the separator will cause the vessel to rotate while the adventitia is thus peeled off until the thin fibrous coat is entirely free from the vessel and may be cut away. After this has been done the vessel is allowed to drop back into its bed and the soft parts are sutured. The operation is followed by immediate changes in the limb, contraction of the exposed vessel, subjective and objective coldness of the extremity, and diminution of the peripheral pulse. These changes last several hours and are followed by signs of dilatation of the peripheral vessels with subjective and objective increase in temperature and elevation of the arterial pulse pressure. These latter phenomena last five or six days or longer. Of the total 11 cases, 7 were of arteriosclerotic origin, 2 were thromboangitic, 1 was a case of trophic ulcer, and 1 was an ulcer complicating mild diabetes. Three patients were completely relieved of pain, 2 were slightly improved, and in 6 no benefit could be seen from the operation. The best results were obtained in patients with pain due to arteriosclerotic disease of the vessels of the legs. Priarterial sympathectomy causes definite changes in the peripheral circulation. The explanation of its action is not clear, and the indications for its use are not sharply defined. Success and failure were met with in seemingly similar cases.

To René Leriche belongs the credit of introducing this operation, an early if not the first case of which was reported by him in *La Presse Médicale* of 1920. The arterial decortication was done for the cure of an intractable ulcer in an amputation stump and was eminently successful. In a later communication (*Annals of Surgery*, October, 1921), he reported a number of successful sympathectomies for the relief of causalgia, Raynaud's disease, and various trophic ulcers. A. E. Halstead has reported a case diagnosed as one of endarteritis obliterans cured by Leriche's operation (*Journal Am Med Association*, January 20, 1923, lxxx, 3). Handley suggests periarterial injection of alcohol as an alternative to this operation (*Lancet*, July 15, 1922, cciii, p 173) and reports a case of incipient gangrene cured by his method.

**A New Method of Approach for the Removal of Deep-Seated Brain Tumors—**Walter E. Dandy (*Annals of Surgery*, October, 1925, lxxvii, 4) presents a method by which tumors (principally ependymal tumors) situated within the brain substance can be exposed and ablated. The procedure involves resection of the so-called silent parts, even, if need be, lobes of the brain. A case is described of a dural epithelioma (a benign encapsulated tumor) arising from the cover of the cribriform plate, and occupying both sides of the cranial

chamber to an equal degree. The tumor was completely removed after a preliminary resection of the left frontal lobe. No loss of function of any kind followed the operation. Resection of a silent cerebral lobe is advocated, in part or whole, as a method for the removal of certain intracranial tumors known to be benign, and which are situated at such a depth as to be in large part or wholly hidden from view. For such tumors situated on the right side of the middle cranial fossa, preliminary resection of the temporal or occipital lobes would be justifiable, though, of course, contralateral homonymous hemianopsia would result. Section of the left occipital lobe posterior to the supramarginal and supra-angular gyri apparently leaves no stigmata other than a right homonymous hemianopsia. The inclusion of these sensory speech areas could hardly ever be justifiable.

The intracranial approach which Dandy describes is designed so as to avoid leaving scars on the forehead in front of the hair line. In a general way it may be said that two small, more or less U-shaped adjoining skin flaps, are used instead of a single large one, a middle limb serving both as the back of the anterior flap and the front of the posterior flap. The base of the anterior flap is directed toward the orbit, the base of the posterior downward toward the zygoma. The principle involved in the use of these two flaps can be variously modified. Dandy has been using this method of approach in practically every case of cerebral tumor or craniotomy for several years.

**The Value of the Leucocyte Count as an Aid to Diagnosis in Ectopic Gestation—**Lilian K. P. Farrar (*Surgery, Gynecology and Obstetrics*, November, 1925, xli, 5) has made observations on the leucocyte count in 150 cases of ectopic gestation, which she summarizes thus: (1) In ectopic gestation the leucocyte count fluctuates according to the amount of fresh blood being thrown into the peritoneal cavity and the rate of absorption. (2) The leucocyte count tends to drop quickly to normal as the blood in the peritoneal cavity is absorbed or walled in, 48 per cent of the 150 cases of ectopic gestation showed a normal leucocyte count before operation was performed. (3) The leucocyte count was normal in 29 cases of unruptured tubal pregnancy in which there was no free blood, and in 43 cases of ruptured pregnancy in which the blood was walled in. (4) The leucocyte count was an index in 150 cases to the amount of fresh blood in the peritoneal cavity and the polymorphonuclear leucocyte count was increased markedly only in cases having fresh blood in the pelvis, and increased in direct proportion to the amount of recent blood found at the time of operation. (5) The fluctuating leucocyte count, together with

the moderate elevation of temperature, differentiates ectopic gestation from a purulent salpingitis with its more uniformly high leucocyte count and fluctuating temperature (6) In cases of rupture of tubal pregnancy the steadily rising leucocyte count indicates active bleeding before the fall in the number of red cells or hemoglobin gives warning of the condition (7) The leucocyte count to be of diagnostic value must be taken at least daily, in critical cases even hourly, and used in conjunction with the history and clinical findings in the case

**Biologic Testing of Ovarian Preparations**—Zondek and Bernhardt of the Charite Hospital, Berlin, refer to the disadvantages inherent in ovarian substance in contrast with the thyroid, adrenal and pancreatic secretions, all of which contain active hormones which permit of a biological standardization It is evident that somehow a hormone must be present to explain the results of ovarian grafting We know beyond doubt that at least one dynamic action can be assigned to ovarian substance, for when castration has lowered the oxygen consumption of the woman by about 15 per cent, ovarian substance will sometimes make this deficit good again We may therefore assume that there is a hormone-like substance in the ovary and that its function is to stimulate oxidation. A clinical case is reported to show that ovarian substance can cause the return of normal oxidation, although to demonstrate this truth it was necessary to supervise the metabolism of a castrated woman for two years or more Before using the home made preparation several marketed preparations were tested and found quite inert Modes of preparation and handling may, therefore, be at fault. The authors are at present endeavoring to determine the identity of the hormone and isolate it—*Klunische Wochenschrift*, October 15, 1925

**Exanthema Subitum**.—Seen originally in St Louis by Zahorsky and described by him under the name of roseola infantilis, in 1910, this affection was recognized later in Ann Arbor, New York, Cleveland, Houston and Detroit. The first European cases were identified in Berne in 1919, and quite recently cases have been studied in Italy So far as known the affection has never been seen in Great Britain, France, or Germany Von Bokay of Budapest, who has seen 11 cases (*Deutscher med Wochenschrift*, Oct 11, 1925), regards exanthema subitum as an autonomous affection His own, like the cases seen by others, are remarkably true to type The fever sets in suddenly in the midst of health and the patients remain relatively well despite the four days of fever which may reach 104°, and which usually ends on the fourth day by crisis Relapses may occur of the same length as the first attack. The

rash is of the measles type and always appears on the trunk, in certain cases also involving the head and extremities Authors have noted congestion of the buccal mucosa and pharyngitis. The younger children seem more predisposed and while cases occur in massed incidence, contagiousness is feeble if present at all The affection is of no great clinical significance, but might of course mask some more serious condition Von Bokay says nothing of any causal factors and mentions no microorganisms The name bestowed on the disease was given in recognition of the suddenness with which the rash appears

**Respiratory Catarrh in Children**.—The frequency of catarrhal troubles in the newborn is a matter of common observation, nevertheless one will read with surprise that one-half of all infants from three to six weeks of age suffer, in England at least, from nasal or bronchial colds This is the statement made by Richard C Clarke (*Lancet*, October 24, 1925, ccix, 5330), who found in a study of his last 1,000 case-sheets that 499 young infants were already affected, and on questioning the mothers the usual answer was "Yes, 'e was born with it" These early infections tend to become chronic and are undoubtedly the cause of inadequate suckling, due to nasal obstruction, of the disease known as "tonsils and adenoids," and of chronic sinus troubles Of over 400 babies under four weeks old, who had nasal catarrh, the writer found that every one had signs of bronchial catarrh Once a child is bronchitic, every fresh cold causes exacerbation of the bronchial signs and symptoms The result is the bronchitic schoolchild and later the bronchitic adult The bronchitic child is severely handicapped, for attacks of bronchopneumonia occur with frequency, while measles, whooping-cough, and even the administration of an anesthetic present added risks in such a case The question of pathogenesis is bound up with the factors which control the spread of infectious disease In order to prevent this condition, the morbid dose of catarrhal organisms on the respiratory mucous membranes must be postponed as long as possible There can be no fear of the child missing the submorbid or immunizing dose In order to avoid the morbid dose the mother should carry out antepartum nasal hygiene, and after delivery if she has acute catarrh, she should wear a folded handkerchief over the mouth and nose when attending the baby The same precaution should be adopted by nurses or other attendants To avoid the other main avenue of infection, the germ-laden atmosphere, is not difficult in the uncrowded house, but if the infant belongs to the overcrowded class it should either be kept out of doors or in a draught The latter point is insisted upon by the author who implies that children do not suffer discomfort from a moderate degree of cold

**Glossitis As One of the Early Prodromes of Pernicious Anemia**—Tilger-Beckers of the surgical division of the Dental Institute of the University of Berlin traces the history of this subject from the original description of the disease by Biermer in 1868 (*Correspondenz-Blatt für Zahnärzte*, 1925, xlix, no 9). It was not until 1909 that William Hunter gave the subject a monographic consideration by collecting 112 cases of glossitis as an early symptom of the disease in question. In 1902 the same author had described a dozen personal cases and in 1909 he stated that in 75 cases of pernicious anemia seen during the preceding seven years every patient exhibited this glossitis. In Germany, Schaumann announced (1912) that in both Biermer's and tapeworm anemia there was a recurrent soreness of the mouth and throat. Others described subjective symptoms, burning of the tongue, which pursued a periodical course. These mostly subjective cases corresponded with the more objective finds of Hunter (although the latter sometimes speaks of "sore tongue" himself). The more recent German observers, as Zimmermann in 1917 and Sackheim in 1922, fully bear out the claims of Hunter that every case of true pernicious anemia exhibits the glossitis as an early symptom. Hunter even goes so far as to call Biermer's anemia "glossitic anemia." But apparently the general practitioner as a class has not yet grasped the diagnostic significance of this early glossitis. Subjectively the organ burns during eating and is very sensitive to acids and salt. Some patients are forced to give up smoking and lose their taste for spirits. The objective symptoms vary much with the stage of the disease, but as we are interested here only in the early stage, they are limited then to an intensive hyperemia with separate small foci of inflammation and disappearance of some of the papillae.

**Treatment of Bubonic Plague by the Bacteriophage**—D'Herelle, who discovered the bacteriophage at the Pasteur Institute, was sent to Indo-China in 1920, where he made a number of most virulent cultures of plague bacilli. *B. pestis*, like the dysentery bacillus, was regarded by him as peculiarly adapted for "phage" treatment, and as from small beginnings the latter made good on a large scale for bacillary dysentery it seemed reasonable to look for favorable results in plague treatment. As the latter disease was endemic in Indo-China the author expected to test his phage cultures upon it, but was ordered to Egypt and forced to entrust the task to a resident colonial surgeon with whom he left a number of ampoules. The next plague cases were given the phage culture, but also received the antiplague serum, so that the favorable outcome of the treatment could not be properly credited. D'Herelle remained in Egypt for a considerable time during which there was a small outbreak of plague. He

had his original cultures of the plague bacillus and prepared a new stock of the phage cultures which were tested on four patients, all of whom made good recoveries, although the disease has a notoriously high mortality. One injection within the first twenty-four hours seemed to be all that it was necessary to give, but if the disease is seen at a later period—as in one of the author's cases—the first injection should be repeated, once or twice if required. The virulent culture of the bacillus should be harmless as soon as the phage develops, and before testing it on patients the author tested it not only on laboratory animals but on his own person. There was no general reaction and the local reaction was inconspicuous. The author recommends for bubonic plague an early injection directly into the buboes. Should the phage cultures be tested in cases of pneumonic plague they would have to be given intravenously.—*La Presse Médicale*, Oct. 21, 1925.

**Apparent Cure of Choked Disc**—Heine of Kiel refers to cases of this affection in which there was no indication for trepanation, and in which the precise etiology was often obscure. Seventeen patients were treated indiscriminately with lumbar puncture, tuberculin and iodine. Two patients who seemed to have entirely recovered were adjudged to have suffered only from the so-called spurious papillitis, and were left out of consideration. The other fifteen patients were reckoned as apparently cured or with disease arrested, bearing in mind the axiom that the longer the observation period the smaller the proportion of actual cures. In regard to the nature of the lesion, seven out of fifteen of the patients were set down as having multiple sclerosis, two others were old syphilitics and one had a cerebellar lesion.—*Muenchener med. Wochenschrift*, September 18, 1925, lxxii, 38.

**Treatment of Rheumatoid Arthritis by Intramuscular Injections of Guaiacol, Iodine and Camphor**—S. Watson Smith (*British Medical Journal*, October 10, 1925, ii, 3380) reports that in nine cases of rheumatoid arthritis and articular fibrositis, other than of postinfective, gouty, or gonorrheal origin, he has obtained satisfactory results by the use of intramuscular injections of 10 per cent guaiacol, 10 per cent iodine, and 5 per cent camphor in oil, the camphor being added for its stimulating and analgesic effect. The initial dose was 0.25 cc and the scale quickly mounted until 1 cc was reached, this was then repeated every third day, or, when thought necessary, every second day. In no case was there any serious general reaction or after-effect. The author finds no record of the previous use of this method in rheumatoid arthritis.

# LEGAL

By **GEORGE W. WHITESIDE, Esq.**  
Counsel, Medical Society of the State of New York

## THE GOVERNMENT OF A PROFESSION

### III

We have previously referred to the operation of the Grievance Committee of the Bar Association of the City of New York as an example of effective government of the legal profession in New York County. Whilst that Association had during the period from 1913 to 1923 an average membership of about 3,000 members, the Grievance Committee considered and acted upon complaints against lawyers irrespective of their affiliation with the Association. In that period that Committee received 9,484 complaints, held 630 meetings, tried 703 cases, and presented to the Appellate Division for disciplinary action 267 cases. The Appellate Division disbarred 140 lawyers, censured 32 and suspended 42 from practice. To accomplish this work during that period the Committee had \$131,468 of net expense.

It is apparent that approximately 8,781 complaints brought were either adjusted by the Committee without trial or found to be without merit. It is likewise apparent that the innocent lawyer complained against received justice and the guilty were punished.

It is a record of this kind in the government of a profession doing justice to the accuser and the accused that has made the Grievance Committee of this Association enjoy public and professional confidence and support.

A separate committee has taken care of the prosecution of unlicensed practitioners of law and in that connection excellent results have been accomplished.

In the handling of this bulk of complaints, to accomplish these results, the cost has been on an average of \$14 a complaint. It seems to have been money well spent.

For almost one hundred years each incorporated medical society has had a board of censors and up to 1887 the functions under the law of the censors were "carefully and impartially to examine all students who shall present themselves for that purpose and report their opinion in writing to the president of the said society." The censors having been denuded of their examining authority by statute have become, through amendments, not of the law but of the constitution and by-laws of county and state medical societies, vested with functions of a disciplinary character. These functions do not extend beyond the exercise of disciplinary power against the members of such societies, and such powers are

restricted to the extreme penalty of dismissal of a member from membership.

It is true, however, that since 1907, under the law, there is nothing to prevent such board of censors from taking the initiative in the bringing of charges before the regents, but this policy has not been followed. The lack of power of the censors adequately to deal with complaints of the public and do justice as between accuser and accused, seems to be the weakness of a system of government of the medical profession through the agency of the boards of censors. As between physician and physician, in the settlement of ethical questions, the censors have functioned in many counties with effectiveness, and for many years in the County of New York the censors were the prosecuting agency to bring unlicensed practitioners of medicine to justice. Over a five-year period, between 1915 and 1920, the censors of the New York County Society considered complaints against 499 unlicensed practitioners and 107 complaints against registered physicians. The performance of this work in the absence of adequate legal machinery became too onerous and expensive to be continued.

When by statute in 1907 the board of regents were given jurisdiction over the practice of medicine with power to try licensed physicians and revoke their licenses, a step was taken in setting up machinery for the government of the medical profession. The judicial power so conferred upon this distinguished body was, however, one quite foreign to the powers which were granted to that body by the constitution of 1784 and which from time to time were confirmed by later constitutional provisions. The regents establish and maintain educational standards and supervise the operation of educational institutions and very properly they determine educational requirements for entrance to the various professions. They are a body in this state particularly who have earned high regard and public confidence. They are a body, however, of laymen who do not have that intimate touch with the problems of medical practice and professional ethical standards of medicine that are so well understood by medical men. They do not even attempt to function in disciplinary proceedings of medical men, except through a committee of the board of medical examiners. Whatever disciplinary functions have been exercised by the regents since 1907 have been, as far as the writer can discover, the revocation of certificates of physicians who have

been convicted of felony. This procedure is purely formal as the law operates itself to work such forfeiture. This body is not constituted nor has it had the background to act as a grievance committee of the medical profession, and with its multitudinous educational functions and duties there is serious doubt whether they would wish to exercise such power.

With the legal profession there has been a negligible amount of court action by clients against attorneys, with the medical profession there has been a constantly increasing amount of such litigation by patients against physicians. Over a period of ten years less than three per cent. of the complaints sent to the Grievance Committee of the Bar Association resulted in disciplinary proceedings against the accused in the Appellate Division. Had there been no such committee through which to filter out and discard the unmeritorious complaints and to segregate for action those justifying court proceedings, the aggrieved parties in large numbers of the 9,484 during the ten-year period would doubtless have resorted in the first instance to the filing of charges against attorneys with the Appellate Division direct. Such a procedure would have resulted in great publicity and injustice to many of the accused and unnecessary expense in defense.

Many cases now brought against physicians for alleged malpractice find their origin in the

desire of the dissatisfied and sometimes unscrupulous patient to vent his ill-will against a physician by causing him worry, anxiety and unpleasant publicity by instituting an action against him in the courts. Many such complaints could be heard by a commission on discipline of the medical profession as proposed in the bill recently submitted by the Medical Society of the State of New York and the merits resolved by the application of principles of truth, ethics and justice, rather than by appealing to a lay jury in court upon grounds of sympathy, prejudice or bias.

The great cry for years among the medical profession has been against the invasion of the realm of medical practice by the unlicensed brigands without. The protests against this unlawful practice have been ineffective in creating sufficient public sentiment to bring about adequate prosecution of the offenders. A system of adequate government of the profession within the profession should tend to elevate the standards of the profession, to protect the honest practitioner against the unfair competition of the unscrupulous and dishonest practitioner, should gain public support and confidence in the profession as a whole and should give to the profession's efforts to repel the invasion of the unfit and unlicensed such support, such confidence and such sanction as should make the practice of medicine by the unlicensed a problem easier to combat and more sure of solution.

### COLLES' FRACTURE

A woman of advanced years by a fall sustained a fracture of her left arm.

In an action of alleged malpractice it was charged that the defendant physician failed to discover the true condition of the patient's injury and negligently treated the fracture, resulting in a malformation of the injured member, causing the plaintiff to expend monies for further medical care and attention and preventing her from following her usual occupation for a period of about fourteen weeks. It was also claimed that the patient's injury was permanent in its nature and that the defendant physician had had X-rays taken of the injured arm but, upon demand from the patient, had refused to deliver the negative films to the patient.

The defendant when called to the patient's home, found that she was suffering from a Colles' fracture. After examination he had X-rays made of the injured wrist and in consultation with the roentgenologist reduced the fracture, applying proper casts. Inspection was made of the injured arm from time to time and after about four weeks, upon examination, the injured wrist was in good condition, with perfect supination and pronation of the hand. Thereafter callus formed at the site of fracture, at which fact the patient became disappointed and thereupon instituted an action of malpractice.

After numerous attempts by plaintiff's attorney to procure a settlement, the action coming on for trial a discontinuance was consented to, terminating the action in favor of the defendant.

## NEWS NOTES

### MEDICAL SOCIETY OF THE COUNTY OF OSWEGO

The 105th Annual Meeting of the Medical Society of the County of Oswego was held on Tuesday, November 17th. The meeting was well attended and the papers and discussions were of unusual interest.

The following officers were elected for the year 1926:

President, Arthur W. Irwin, Vice-president, Earl A. Mowry, Secretary, W. H. Kidder, Treasurer, Joseph B. Ringland, Delegate, Frank E. Fox, Censors, Frank E. Fox, Le Roy F. Hollis, Frederick W. Manly, David D. O'Brien, Frederick L. Sinclair.

A resolution was passed directing the adoption of the automobile emblem of the A. M. A. with the County Society's insignia incorporated.

A resolution directed the President to appoint physicians for service as examiners in the prospective pre-school age clinics of the State Department of Health.

In discussion of the matter of post-graduate study for members of the Society, attention was called to the fact that many physicians of the County are more accessible to Syracuse than to centers in the county, and that it might be better to make arrangements for physicians to investigate the possibility of having proper post-graduate training there. The matter was tabled.

A resolution of appreciation to the speakers was passed.

The administration of Dr. A. L. Hall having been particularly successful with two of the most interesting meetings ever held in the history of the Society, and with speakers of unusual prominence and ability, a resolution of commendation and appreciation was passed. Dr. Hall takes with him from office the gratitude of all who have attended the meetings arranged by him.

The paper presented by Dr. Haviland excited particular interest because it dealt in a most practical way with conditions which force themselves on the attention of all physicians, general practitioners and specialists alike. The paper not only clearly explained many of the not commonly understood factors in cerebral arteriosclerosis, but in a simple and painstaking way told us how to differentiate our cases and how to administer the right lines of treatment to the different classes. A resolution was introduced and unanimously passed asking that Dr. Haviland submit his paper for publication in the State Journal.

The paper of Dr. Potter was interesting and presented in a most fascinating manner. The discussion following its presentation was no less lively than those in other societies which have come after the presentation of similar papers by Dr. Potter. Regardless of the merits of the methods followed by this obstetrician, the Society feels deeply in his debt. Apart from his personal technique, he made statements which clarified numerous obstetric problems and which cannot but set us who heard him to thinking. All in all, his paper can be put down as one of the most valuable ever given before this Society.

As a somewhat novel feature of the meeting a supply of the various brochures issued by the State Department of Health, some from the press of the National Government, and numerous volumes and brochures published by the A. M. A. were on exhibit, with a nurse in attendance. The object was to more intimately acquaint physicians with the publication activities of these various agencies, and to show them what rich fields they had from which to draw material for their waiting-room tables. The exhibit included a copy of the last Directory of the A. M. A. and one of "The Medical Follies."

### BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society was held at Hollywood Gardens, November 18, 1925. The meeting was called to order at 9 P. M., the President, Dr. Jacobs, in the Chair.

Election of candidates for membership being in order, it was moved and carried that the Secretary be instructed to cast one ballot for the following applicants for membership:

Drs. Joseph S. Brandstein, Daniel J. Dolan,

Joseph Epstein, Frederick L. Flynn, Max Pensak, Reuben Rapoport, Daniel F. Shields, James Sager Threlkeld.

Dr. Simeon A. Jacobs was reinstated.

Dr. L. A. Friedman, for the Committee on Public Health, reported with special reference to the proposed Periodic Health Examinations.

Dr. Cunniffe reported for the Building Committee. He stated that the members of the Comitia Minora and of the Building Committee have

pledged themselves to contribute to the Building Fund and urged the cooperation of all the members

Nomination of Officers for the year 1926 being in order, nominations were made for the Offices of President, First Vice-President, Second Vice-President, Secretary, Corresponding Secretary and Treasurer, and for the Board of Censors, Delegates and Alternates

It was moved and carried that the motion passed at the last meeting of the Society that a Special Meeting be called to consider the proposed By-Laws and the Building Fund be reconsidered and that we take up these matters at the regular December meeting of the Society

The Scientific Program then proceeded as follows

Diseases of the Nose and Throat of Special Interest to the General Practitioner, Sidney Yankauer, M D, New York

Otology in Relation to General Medicine, I M Heller, M D, New York

Diseases of the Eye in General Medicine, Percy Fridenberg, M D, New York

Moved, seconded and carried, that a vote of thanks be extended to the readers of these excellent Papers. The President expressed the appreciation of the Society to Drs Yankauer, Heller and Fridenberg

### ROCKLAND COUNTY MEDICAL SOCIETY

A special meeting of the Rockland County Medical Society was held at the Rockland Country Club, Sparkhill, on Wednesday, October 21st, 1925. Twenty-one members were present and the two candidates for Member of Assembly

Dr James A Kearney, attending ophthalmologist to the New York Polyclinic Hospital and the New York State Hospital for Crippled Children, reported a case of true filial teratoma and cyst in the orbit of a new-born child. There have been ten such cases reported in Europe, the last one 15 years ago. However, Dr Kearney's case is the first one to be reported in America. The child was seen ten minutes after birth and operation was performed three hours later. The mass was removed, leaving the entire eyeball intact. A series of most interesting lantern slides was exhibited, showing photographs of the child before, during and after the operation. Examination 1½ years later showed normal pupillary response and apparently normal vision. Dr Toms and other members of the Society thanked Dr Kearney for the privilege of listening to the

presentation of such a rare case, but said they were not in a position to discuss it

Dr George W Kosmak, attending surgeon to the New York Lyng-In Hospital, gave some very practical points on the conservative treatment of toxemias of pregnancy. His address was most comprehensive, covering as it did every phase of the subject, from the nausea and vomiting of early pregnancy to the method of handling cases of eclampsia

Dr Kosmak's paper was discussed by Drs Kline, Leitner, Sly and Dougherty

A rising vote of thanks was extended to the two speakers, and on motion both Dr Kearney and Dr Kosmak were made honorary members of the Society

An excellent chicken supper was served by the Steward of the Club. The medical practice bill was discussed by Dr Leitner, and both candidates for member of assembly expressed their willingness and determination to support and fight for the passage of the new bill

### MEDICAL SOCIETY COUNTY OF ESSEX

The Annual Meeting of the Essex County Society was held at the Lee House, Port Henry, October 6th, 1925

The President appointed the following Nominating Committee: Drs L G Barton, Jr, T J Cummins, T J Dowd

The following were placed in nomination

For President: Peter Noe, Willsboro, Vice President: W T Sherman, Crown Point, Secretary-Treasurer: H J. Harris, Westport, Censors: R T Saville, C B Warner, T J Cummins, Delegate to State Society: J P J Cummins, Alternate Delegate to State Society: M E Sargent

On motion duly made, seconded and unanimously adopted the Secretary cast one ballot for

the election of these officers. Motion made and seconded that the annual meeting of the Society be held at Moses-Ludington Hospital at Ticonderoga beginning with the 1926 meeting, to be voted on at the next meeting

#### Scientific Session

President's address—Dr A Gersen, retiring President

Derangements of the Knee Joint with operative technique—G W Turner, Orthopedic Surgeon, Royal Victoria Hospital, Montreal, P Q

Surgical Gallbladder—J P J Cummins, Ticonderoga

Certain Diseases of the Eye—H Gaus, Ticonderoga

# THE DAILY PRESS

## ARE DOCTORS REACTIONARY?

When any one wishes to promote a new system of healing he has no difficulty in finding destructive criticisms of the medical profession made by physicians who are eminent in their profession. A religious tract bearing the marks of sincerity has lately come to us. It urges sinners to seek health from Divine rather than medical sources. It quotes thirty medical authorities to show the helplessness of medical science, and the disconcerting point about it all is that many of the authorities were in reality eminent. Dr. Oliver Wendell Holmes is quoted as saying "I fairly believe that if the whole *materia medica* could be sunk to the bottom of the sea, it would be all the better for mankind and all the worse for the fishes." This is a sample of extravagant statements actually made by prominent physicians, giving the impression that the practice of medicine rests on a foundation of untruth. If the medical writers had thought about the effect of their statements, they would have been more careful to express their meaning accurately.

The newspapers of New York City have given wide publicity to the remarks by an eminent public health worker before a two day conference of public health workers in which he criticized the medical profession for not giving proper attention to public health. The *Herald-Tribune*, November 21, says that this doctor "regretted that no medical organization of New York had co-operated with the six health bodies which were responsible for the conference," and that

he admitted that there had been encroachments on the part of health workers on the medical field, but rebuked the physicians for jealousy and ignorance of public health needs."

It is to the credit of the metropolitan newspapers that they generally printed this as news with little or no comment. The editorial writer of the *Patchogue Advance*, November 27th, takes up the active defense of the doctors and says

"We are fond of thinking how modern science is wiping out plagues and extending the field of preventive medicine. It is then with something of a shock that one reads that too many physicians look with coldness on modern discoveries. In consequence, only a limited number of people are receiving the best that science can afford."

"It is to be hoped that the doctor in his zeal to have his profession do its utmost for mankind, makes too sweeping statements and thus discredits some worthy doctors who are above the criticism he offers. But his warning will not do any harm. A physician should be a student to the end of his days, and should be able to employ every form of diagnosis and every remedy that has got beyond the purely experimental stage."

To physicians the statements of their eminent critic sound like scolding, and to unfriendly critics of the medical profession they appear to be indictments of doctors generally. This question is further discussed in our editorial pages.

## BACTERIOPHAGES

The *Brooklyn Daily Eagle*, November 13, has an editorial on "The Elusive Bacteriophage." How many readers of the *Eagle* will know what a "bacteriophage" is? The more thoughtful will turn to the English dictionaries,—Webster's, or *The Standard*, or *The Century*,—and they will not find the word listed.

Doctors are accused of using long technical words, but they seldom use the word "bacteriophage" even in their technical writings. There are a few medical words, such as "*streptococcus*" and "*poliomyelitis*," which have come into common use because no every-day words existed to denote the popular meanings of those words. Physicians to-day are using familiar terms as much as possible. It is the dressmakers and carpenters rather than the doctors who are given to the use of unfamiliar technical terms.

The editorial writer uses the term "bacteriophage" to denote a universal destroyer of internal parasites in the human body. The principal point which he makes is that American investigators are too cold toward alleged foreign discoveries for the prevention of disease. He cites two examples of what he calls "American indifference." First he mentions "A lytic principle got from sewage-filled water," which is "efficient as against the dysentery, the typhoid, and the paratyphoid bacteria, and therefore of inestimable value to the physician." It is of course difficult to know just what the lay editorial writer had in mind, but he probably read something about the details of an investigation into the exact cause of the well-known fact that virulent disease germs in sewage usually die and disappear in the course of putrefaction and decay in a

cesspool or disposal plant. Their disappearance from sewage under natural conditions is of great public health importance, but that phenomenon has no bearing on the destruction of the germs inside the human body.

The second example of "American indifference" quoted by the editorial writer is an alleged cure of cancer by injections of lead. The writer remarks that a prominent American investigator in cancer says "coldly" — "I have experimented with it extensively, and found nothing in it that offered any definite hope in the treatment of cancer."

The writer then comments — "The layman is inclined to wonder if the healing science would not be more advanced in this country if more of enthusiasm and less of skepticism greeted the discover of other scientists in other lands."

The point of view of the lay editorial writer is that of reports which come to him through newspaper channels. Whenever a foreign investigator makes an apparent discovery, he tries to exploit it in America,—the land of free thought and money. Turtle serum for tuberculosis and artificial pleuritic pus from rabbits for empyema, are two alleged German "discoveries" which were exploited in America until laws were passed forbidding the sale of any serum containing living disease germs unless it was manufactured under the strict supervision of the United States Public

Health Service. America is entirely too hospitable toward investigators who have advertising press agents.

The fact that American investigators welcome information from whatever source,—German, French, Japanese, or otherwise,—leads the self-advertisers to come to this country. American physicians have given enthusiastic support to Behring for his diphtheria antitoxin, to Wasserman for his test for lues, to Ehrlich for his salvarsan, and to Schick for his toxin-antitoxin protection against diphtheria.

Science knows no nationality, and the methods and results of investigations are fully revealed in technical journals which have a world-wide circulation among scientists. Journals published in German, French, Japanese, and Spanish are found in every American research laboratory, and their volume exceeds that of the Journals published in the English language.

The greatest amount of complaint of the coldness of Americans toward outside workers comes from those foreigners who are denied admission to the scientific journals of their own countries. When these incompetent workers complain to the lay press, they entirely misjudge the attitude of American investigators whose unselfish ideals, modesty, and honesty are as high as those of any other nation. To complain to the newspapers is the surest way to ruin the reputation and standing of an aspiring scientific worker.

## QUARANTINE ON NARCISSUS BULBS

Physicians can appreciate the motives of the Federal Horticultural Board of the Department of Agriculture in placing a quarantine on the importation of narcissus bulbs, on the ground that they are likely to be infested with larvæ of a fly which might threaten onion and alfalfa plants as well as narcissus bulbs. The Garden Club of America is protesting against the quarantine, according to an editorial in the *Brooklyn Eagle* of November 18th, on the grounds that there is no evidence of an emergency, that the Holland growers are taking "the most intelligent precaution that long experience can offer", and that the immediate money loss will be great if the bulbs cannot be imported.

Doctors know how difficult it is to prevent the admission of human diseases. It is still more difficult to prevent the admission of insect pests. Most of our noxious insects and weeds are imported foreigners, which do little damage in their home lands because their natural enemies keep them in subjection. The gypsy moth which threatens the shade trees of New England and Eastern New York is harmless in Europe because its natural enemies keep it in check. A few escaped from a Boston entomologist who

kept them for study. He informed the authorities who considered that, since they were harmless in Europe, they would also be harmless here. They multiplied enormously, and all efforts to find their natural enemies have failed. The only way to eliminate them from a district is that of epidemiology—to find every moth nest and destroy it.

More fortunate was the measure taken against the Japanese orange scale that was introduced into California. A ladybug was found that preyed upon the young insects in Japan, and when this was introduced into California, it quickly destroyed most of the scale insects, and then itself died because it found too few scales on which to feed. The Government now grows the ladybugs, in order to release them wherever the scale appears.

If the narcissus fly is introduced into America, there is no assurance that it will not multiply to a dangerous extent, unless its natural enemy, or antitoxin, is brought with it. The Department of Agriculture is to be commended for adopting a plant quarantine that is as effective as the rat quarantine of the United States Public Health Service.

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this columns will be made for review, as dictated by their merits or in the interest of our readers.

**THE RADIOLOGICAL EXAMINATION OF THE MALE URETHRA** By G. L. S. KOHNSTAM, M.R.C.S. (Eng.), L.R.C.P. (Lond.). Preface by SIR JOHN THOMSON-WALKER O.B.E., M.B., F.R.C.S. William Wood & Co., New York. Price \$5.50

**SOME ENCOURAGEMENTS IN CANCER SURGERY** By G. GREY TURNER, F.R.C.S. (Eng.), Honorary Surgeon Royal Infirmary, Newcastle-upon-Tyne. William Wood & Co., New York, 1925. Price \$3.50

**AIDS TO SURGICAL DIAGNOSIS** By CECIL P. G. WAKELEY, F.R.C.S., Assistant Surgeon, King's College Hospital. William Wood & Co., New York, 1925. Price \$1.50

**DISEASES OF INFANTS AND CHILDREN** By HENRY DWIGHT CHAPIN, A.M., M.D., Consulting Physician New York Post Graduate and Willard Parker Hospitals, and Lawrence Thomas Royster, M.D., Professor Pediatrics, Pediatric Department of the University of Virginia. Fifth revised edition. William Wood & Co., New York, 1925. Price \$6.00

**THE THERAPY OF PUERPERAL FEVER.** By Privatdozent Dr ROBERT KOEHLER, formerly Assistant Genecological Department Krankenhaus Wieden, Vienna, Austria. American edition prepared by HUGO EHRENFEST, M.D., F.A.C.S., Associate in Obstetrics, Washington University School of Medicine, twenty-seven illustrations. The C. V. Mosby Co., St. Louis, Mo., 1925. Price \$4.00

**A TEXTBOOK OF PHYSIOLOGY** By WILLIAM D. ZOETHOUT, Ph.D., Professor of Physiology in the Chicago College of Dental Surgery (Loyola University). Second edition. The C. V. Mosby Co., St. Louis, Mo., 1925. Price, \$4.50

**PSYCHOLOGICAL HEALING** A Historical and Clinical Study by PIERRE JANET, Professor of Psychology, College of France. Translated from the French by Eden and Cedar Paul. Two volumes. The Macmillan Company, New York, 1925. Price per set, \$14.00

**A HISTORY OF THE MASSACHUSETTS MEDICAL SOCIETY WITH BRIEF BIOGRAPHIES OF THE FOUNDERS AND CHIEF OFFICERS** By WALTER L. BURRAGE A.M., M.D., Secretary of the Society. Illustrated with views of some of the meeting places, reproductions of old documents and portraits of important officers

**INTRAVENOUS THERAPY—ITS APPLICATION IN THE MODERN PRACTICE OF MEDICINE.** By WALTER FOREST DUTTON M.D., Visiting Physician to the Northwest Texas Hospital. 64 half-tones and line engravings, some in colors. Second revised and enlarged edition. F. A. Davis Company, Philadelphia, 1925. Price \$6.00

**THE MEDICAL FOLLIES** An Analysis of the Foibles of Some Healing Cults, Including Osteopathy, Homeopathy, Chiropractic, and the Electronic Reactions of Abrams with Essays on The Antivivisectionists Health Legislation, Physical Culture, Birth Control, and Rejuvenation. By MORRIS FISHBAIN, M.D., Editor of the Journal of the American Medical Association. Boni & Liveright, New York, 1925

**TREATMENT OF KIDNEY DISEASES AND HIGH BLOOD PRESSURE.** By FREDERICK M. ALLEN, M.D. Part I, Practical Manual for Physicians and Patients. The Physiatric Institute, Morristown, N. J.

**THE HEALING GODS OF ANCIENT CIVILIZATIONS.** By WALTER ADDISON JAYNE, M.D. Emeritus Professor of Gynecology and Abdominal Surgery, University of Colorado. Yale University Press, New Haven, Conn., 1925. Price \$5.00

**ALLERGY, ASTHMA, HAY FEVER, URTICARIA AND ALLIED MANIFESTATIONS OF REACTION** By WILLIAM W. DUKE, Ph.B., M.D., Kansas City, Mo. With 75 Illustrations. The C. V. Mosby Co., St. Louis, 1925. Price \$5.50

**EYE, EAR, NOSE AND THROAT MANUAL FOR NURSES.** By ROY H. PARKINSON, M.D., Visiting Oculist and Aurist to St. Joseph's Hospital, San Francisco, California. Illustrated. The C. V. Mosby Co., St. Louis, 1925. Price \$2.25

**OCULAR THERAPEUTICS** A Manual for the Student and the Practitioner. By ERNST FRANKKE, M.D. Translated by CLARENCE LOEB, A.M., M.D. Oculist to The Michael Reese Hospital, Chicago, Ill. The C. V. Mosby Co., St. Louis, 1925. Price \$3.50

**A SYNOPSIS OF SURGERY** Illustrated. By ERNEST W. HEY GROVES, M.S., M.D., B.Sc. (Lond.), F.R.C.S. (Eng.). Seventh Edition. William Wood and Co., New York, 1925. Price \$5.00

**SYNOPSIS OF MIDWIFERY AND GYNECOLOGY** By ALECK W. BOURNE, B.A., M.B., B.Ch. (Camb.), F.R.C.S. (Eng.). Third Edition, Revised and Enlarged, with numerous Diagrams. William Wood and Co., New York, 1925. Price \$4.50

**PHYSIOLOGICAL CHEMISTRY** A Text Book and Manual for Students. By ALBERT P. MATHEWS, Ph.D., Professor of Biochemistry The University of Cincinnati, O. Fourth Edition. Illustrated. William Wood and Co., New York, 1925. Price \$6.50

**MODERN OPERATIVE SURGERY** Edited by H. W. CARSON, F.R.C.S., Eng., Senior Surgeon, Prince of Wales's General Hospital, Tottenham, Lecturer on Abdominal Surgery, North-East London Post-Graduate College. In Two Volumes, with 735 Figures and 6 Plates. William Wood and Company, New York, 1925. Price \$20.00 set.

**OPOTHÉRAPIE, ENDOCRINIENNE, BASES PHYSIOLOGIQUES SYNDROMES, POSOLOGIE, DE L'OPOTHÉRAPIE PAR LES GLANDES A SÉCRÉTION INTERNE.** Masson et Cie, Paris.

**MANSON'S TROPICAL DISEASES** A Manual of the Diseases of Warm Climates. Edited by PHILIP H. MANSON-BAHR, D.S.O., M.A., M.D., D.T.M., and H. CANTAB, F.R.C.P., Lond. Physician Hospital Tropical Diseases, London, Eighth Edition, Revised. 20 color plates 7 half-tone, 387 figures, maps and charts. William Wood and Co., New York, 1925. Price, \$11.00

**THE NATIONAL HEALTH SERIES** Edited by the National Health Council. Published in 20 volumes by the Funk and Wagnalls Company, New York City. 1924. 16mo. Bound in flexible fabrikoid. Price per set, \$6.00 net, per volume, 30c net.

**PHYSICAL DIAGNOSIS OF DISEASES OF THE CHEST** By JOSEPH H. PRATT A.M., M.D., and GEORGE E. BUSHNELL, Ph.D., M.D. Octavo of 522 pages with 166 illustrations. Phila. and London, W. B. Saunders Co. 1925. Cloth, \$5.00

**SURGICAL CLINICS OF NORTH AMERICA.** Volume 5, Number 3, June, 1925 (Mayo Clinic Number). Published every other month by the W. B. Saunders Co. Phila. and London. Per Clinic Year (6 issues) Cloth, \$16.00, Paper, \$12.00

**MEDICAL CLINICS OF NORTH AMERICA.** Volume 9, Number 1, July, 1925. (St. Louis Number). Published every other month by the W. B. Saunders Co., Phila. and London. Per Clinic Year (6 issues) Cloth, \$16.00, Paper, \$12.00

cesspool or disposal plant. Their disappearance from sewage under natural conditions is of great public health importance, but that phenomenon has no bearing on the destruction of the germs inside the human body.

The second example of "American indifference" quoted by the editorial writer is an alleged cure of cancer by injections of lead. # BOOK REVIEWS

**OLD AND NEW VIEWPOINTS IN PSYCHOLOGY** Some Interpretations and Applications of Psychological Principles By KNIGHT DUNLAP, Professor of Experimental Psychology, Johns Hopkins University The C. V. Mosby Co., St. Louis \$1.50 net.

This is a delightful book of five chapters. The style is clear, and forceful. This seems to be the era for the publication of books on psychology, and on all sides lectures are being given on the subject. The word is frequently heard in all sorts of conversations. The author will isolate the value of many of the arguments on this subject, if the reader will follow him. The value and real basis of the various schools is given in a few easily understood paragraphs. Freud receives the credit, which to our mind is his due.

Observation is a part of clinical medicine. A help on this subject is given in this book. The book is of value for this purpose alone.

We recommend this book to anyone, and am sure that a few hours will be spent with pleasure as well as benefit while reading it. J ARTHUR BUCHANAN

**A COMPEND OF GYNECOLOGY** By WILLIAM HUGHES WELLS, M.D. 5th Edition, revised and enlarged, by WILLIAM B. HARER, M.D. 12mo 371 pages, 167 illustrations. Phila., P. Blakiston's Son & Co 1925 Cloth, \$2.00

This compend is as clear and concise as it is possible for a compend to be. Because of the limited space, statements are made as though final, thus oftentimes leaving the wrong impression. Again space is devoted to a discussion of implements and practices that are in truth obsolete, thus using needed space.

For one who has a good working knowledge of gynecology this little book offers an easy method of review. G W P

**A LABORATORY MANUAL OF PHYSIOLOGICAL CHEMISTRY** By ELBERT W. ROCKWOOD, M.D., and PAUL REED ROCKWOOD, M.D. Fifth Edition, revised and enlarged. Four colored plates, forty-three text engravings. F. A. Davis Co., Philadelphia, 1924. Price, \$4.00 net.

As a Laboratory Manual of Physiological Chemistry this Fifth Revised and Enlarged Edition presents all the valuable features of the earlier ones and has an air of being up-to-date that is refreshing. Special consideration of colloids in relation to metabolism, the ionic theory and hydrogen ion concentration acknowledge the importance of those subjects in the study of Physiological Chemistry as a part of modern medical education.

Its treatment of micro-methods in blood-chemistry, acid-base equilibrium, insulin and vitamins, place it abreast with progress in medical science. The questions asked at the conclusion of each series of related procedures, promote observation and thought on the part of the student who otherwise is so prone to perform his experiments mechanically without appreciating their significance.

The subject-matter is complete and the elaboration of theory in opportune places makes this a well-rounded work. G H R.

**BOOK OF PHYSIOLOGY FOR MEDICAL STUDENTS AND PHYSICIANS** By WILLIAM H. HOWELL, Ph.D., M.D., Sc.D., LL.D. Ninth Edition, thoroughly revised. Octavo of 1069 pages with 308 illustrations. Phila and London, W. B. Saunders Co., 1924. Cloth, \$6.50

As a Text-book of Physiology for medical students this work has, for many years, enjoyed a place second

to none. It is concise, to the point and follows a logical sequence. At the same time, it is sufficiently complete to provide for the student a comprehensive, and yet not burdensomely detailed, source of information. It is a book of science and yet easy to read.

This recent edition as also the others, simply confirms the apparent intention of the author to present a work which has all of the wealth of its forerunners, eliminates that which time has shown to be untenable or irrelevant, and presents that part of the newer matter which safely may be accepted as fact or which is compatible with those of the newer theories and points of view which are most generally acceptable.

The medical student's most bitter complaint is that he has too much to read. The busy physician certainly cannot wade through a mass of material for the information which he must have if he is to keep abreast of the advance in medical science or to review, as he should, its fundamentals. Such a text as this provides a ready source of all that is necessary and the author is to be congratulated in that while he has revised and rewritten, he has not materially added to the length of the book.

While knowledge of the chemistry of muscle contraction is still far from complete, the author has given the student the benefit of the more recent light on that subject, and he has recognized the fact that endocrinology is still whirling in the vortex of a whirlpool of uncertainty, by rewriting large parts of that chapter.

This Ninth Edition is, then, at once concise, in good order, readable, up-to-date and sufficiently comprehensive to make it immeasurably useful to the book-burdened medical student and the all-too-busy physician, as a text-book of physiology. G H R.

**LIFE INSURANCE EXAMINATION** Edited by FRANK W. FOXWORTHY, Ph.D., M.D. Octavo of 738 pages with 156 illustrations. St. Louis, C. V. Mosby Co., 1924

Life insurance examining may almost be considered an essential part of post graduate medical education. A great majority of the physicians of the United States indulge in it at one time or another. Some utilizing it as a crutch to tide them over the first lean years of practice, to be given up as soon as finances permit, others continuing to examine throughout their entire active practice, and a certain few making it a life work. To these physicians this book is dedicated.

It is a collection of monographs contributed by recognized authorities on the various phases of life insurance of interest to the medical examiners. The numerous subjects are excellently presented and the illustrations are profuse. The first part of the book is devoted to a history of life insurance, and to the internal organization of the companies. This is followed by detailed instruction to the examiner, as to his duty to the company, for which he is examining.

Nearly one-half of the work is devoted to the subject of physical diagnosis from a somewhat different point of view. Indeed, this portion of the volume is in itself an elementary text-book on this subject, and is excellently presented.

On the whole "Life Insurance Examination" is a noteworthy and valuable addition to a reference library. It is to be hoped that the editor will present a condensed volume with the inevitable overlappings and repetitions eliminated, which one feels will be even more valuable to the medical examiner. W V M
